Health of Michigan.—Reports to the State Board of Health for September concerning the most prevalent diseases in the state show that in 57 per cent. of the reports rheumatism and diarrhea were mentioned; in 44, neuralgia; in 42, bronchitis; in 39, tonsillitis; in 24, typhoid fever; in 23, cholera morbus and consumption, and in 22 dysentery.

Comparative Morbidity.—For September, compared with the average for September in the last 10 years, pleuritis, scarlet fever and smallpox were more than usually prevalent; and cholera morbus, dysentery, cholera infantum, influenza, intermittent fever, remittent fever, erysipelas, inflammation of brain, meningitis and measles less than usually prevalent.

The Most Dangerous Communicable Diseases.—Meningitis was reported present during September at 8 places, measles at 24 places, whooping cough at 32 places, smallpox at 57 places, diphtheria at 73 places, scarlet fever at 103 places, typhoid fever at 182 places, and consumption at 233 places. Reports from all sources show meningitis reported present at 5 places more, measles at 22 places less, whooping cough at 4 places less, smallpox at 4 places less, diphtheria at 24 places more, scarlet fever at 11 places more, typhoid fever at 55 places more, and consumption at 7 places more, in September than in the preceding month.

September Mortality.—The total number of deaths reported for September was 2,722, or 78 less than the number for the preceding month. The death rate was 13.4 per 1,000 population. There were 682 deaths of infants under 1 year of age, 233 deaths of children aged 1 to 4 years, and 730 deaths of persons 65 years and over. Important causes of death were as follows: tuberculosis, 184; typhoid fever, 74; diphtheria, 42; scarlet fever, 6; measles, 2; whooping cough, 22; pneumonia, 38; diarrhea and enteritis, under 2 years, 408; cancer, 154, and violence, 163. There was 1 death from smallpox. Typhoid fever increased somewhat in mortality, as is usual at this time of the year. The number of deaths for the month was less than the number reported for the corresponding month last year.

MINNESOTA.

Lauds St. Paul's Health.—St. Paul's death rate is reported to be 9.2 per 1,000, and the health commissioner boasts that it is the most healthful city in the United States.

Presentation.—In honor of the thirty-second anniversary of the arrival of Dr. Charles Simpson in Minneapolis, a number of his professional friends met at his house and presented him with a gold-headed cane.

Would Bar Out Trachoma.—Ramsey County Medical Society has passed a resolution urging the St. Paul School Board to prohibit pupils suffering from trachoma or any other infectious diseases of the eyes from attending the public schools.

Academy of Medicine Election.—At the annual meeting of the Minnesota Academy of Medicine, held October 7, the following officers were elected: President, Dr. William Davis, St. Paul; vice-president, Dr. James H. Dunn, Minneapolis, and secretary and treasurer, Dr. Arthur W. Dunning, St. Paul.

The New College Year.—The medical department of the University of Minnesota opened September 8, with an address

by Dr. Alexander J. Stone, St. Paul.——The College of Physicians and Surgeons, Hamline University, opened for its twenty-first school term, September 27, with a lecture by Dr. Charles W. Malchow, Minneapolis.

NEW YORK.

Pavilions for Insane Consumptives.—Governor Odell has approved the plans and specifications for the new tuberculosis pavilions to be erected at the Utica, Binghamton and Middletown state hospitals.

Against Tetanus.—Dr. Louis C. Ager, chairman of the Committee on Public Health and Medical Charities of the Kings County Medical Association, has sent to the various chairmen of the county associations a request to influence the members of the legislature and the local newspapers for the passage of an antitetanus bill at an early session of the legislature. The Buffalo Academy has, as previously reported, already taken action on this subject.

Alumni Dine and Hold Election.—The Central New York Alumni Association of Albany Medical Colleges held its third annual meeting and banquet in Utica, September 30. The following officers were elected: Dr. Merritt B. Fairchild, Syracuse, president; Drs. Arthur C. Hagedon, Gloversville, Otis H. Deck, Herkimer, Leroy F. Hollis, Lacona, Ward E. Hunt, Little Falls, Israel M. Slingerland, Fayetteville, and William T. Hudson, Auburn, vice-presidents; Dr. Frederick H. Brewer, Utica, secretary, and Dr. A. Wieting Hedding, Syracuse, treasurer.

New York City.

Personal.—Dr. Joseph B. Bryant, who visited Chicago with ex-President Cleveland, held two clinics while there at Mercy Hospital, October 16.

Norwegian Hospital Staff Changes.—Dr. R. G. Moore has resigned and will take a service in the Orthopedic Hospital, Manhattan.——Dr. W. R. Hersman succeeds him, and the place of the latter as assistant has been filled by the appointment of Dr. L. W. Stork.

Day Treatment for Tuberculosis.—At the Metropolitan Hospital, Blackwell's Island a day-treatment system has been instituted in the tuberculosis department, whereby the female patients remain at the island during the day and are given the open-air treatment, together with medicine and good food.

Hospital for Consumptive Children.—Mr. John Seeley Ward, Jr., of the Association for Improving the Condition of the Poor, has returned from a trip abroad full of the determination to see what can be done toward establishing a seaside hospital large enough to care for at least 100 tuberculous children. He states that at the hospitals visited by him in the vicinity of Paris 29 per cent. were cured.

Asks for More Inspectors.—President Lederle of the board of health has asked the board of estimate for an appropriation for 1904 of $1,631,500, an increase of $597,108 over the appropropriation for 1903. Of this $190,612 is needed for an enlargement of his staff, and part will be expended in providing for a summer corps of physicians for house-to-house inspection in tenement districts. He wishes also to appoint more inspectors for the prevention of contagious diseases; to look after the food and milk supplies, and to visit the factories and other places where children are employed and for the suppression of glanders.

Alleged Conspiracy to Evade Medical Examination of Immigrants.—Mr. Broughton Brandenberg, who has just returned from Italy as a steerage passenger in order that he might study the conditions of Italian emigrants coming to this country, has just unearthed what he believes to be a conspiracy, which directly affects the public health. He had with him a party of emigrants, and while they were waiting on the wharf at Naples to have their baggage examined and fumigated, they were approached by a man who offered for $5 to put through all their baggage without medical examination. After some parleying his services were accepted, and he proceeded at once, with the aid of assistants, to place counterfeit pasters on the baggage. A lead tag indicates that the baggage has been fumigated, a red label that the emigrants have passed the Italian government officials, and the red label that the representative of the United States consul has seen the other labels affixed. Our own officials accept this evidence of medical inspection of emigrants except as regards the head and eyes. After the party and baggage had been passed on board the steamer, Mr. Brandenberg informed the consul, and as a result three of the men were arrested. On them were found a large number of the counterfeit seals and pasters, and on searching the baggage on the vessel it was discovered that 68 out of 140 pieces were provided with these counterfeits.

Buffalo.

Personal.—Dr. Montgomery A. Crockett has returned from Europe.——Dr. Allen A. Jones has returned from Big Moose Lake in the Adirondacks.

Hospital Moves.—The Riverside Accident Hospital has removed into its newly-renovated home on Swan Street, where all emergency cases can be attended to.

Club Election.—The Roswell Park Medical Club elected as president Dr. Frederick C. Busch; vice-president, Dr. James A. Gibson, and secretary-treasurer, Dr. George F. Cott.

OREGON.

Personal.—Dr. DeWitt A. Paine, Eugene, has retired from practice and will move to Portland.——Drs. David H. Rand and George Ainslie and wife of Portland have returned from Europe.

State Needs Institute for Feeble-Minded.—The Oregon State Medical Society, at its recent meeting, favored the maintenance at state expense of a feeble-minded institute separate from the present State Insane Asylum at Salem.

State Society Elects Officers.—At the thirteenth annual meeting of the Oregon State Medical Society, held in Portland, September 29 and 30, the following officers were elected: President, Dr. Walter T. Williamson, Salem; vice-presidents, Drs. George W. Tape, Hot Lake, Elmer E. Ferguson, The Dalles, and Mae H. Cardwell, Portland; treasurer, Dr. Jessie W. McGavin, Portland; secretary, Dr. Luther H. Hamilton, Portland; councilors, Drs. Simeon E. Josephi, R. C. Coffey and George F. Wilson, Portland, and Calvin S. White, Gervais, for one year; Drs. William J. May, Baker City, and Jacob A. Fulton, Astoria, for 2 years; Drs. William F. Amos, Portland, and William House, Pendleton, for three years, and Drs. Walter T. Williamson, Salem, and Samuel T. Linklater, Hillsboro, for 4 years; delegate to the American Medical Association, Dr. Charles J. Smith, Pendleton, and alternate, Dr. Kenneth A. J. Mackenzie, Portland.

PENNSYLVANIA.

Personal.—Orders have been issued appointing Dr. Henry Norris, Philadelphia, assistant surgeon of the Third Regiment Pennsylvania National Guards, with the rank of first lieutenant.

Hospital Day at St. Luke's.—St. Luke's Hospital, South Bethlehem, Pa., celebrated "Hospital Day" October 17. An address was delivered by Dr. Edward Wallace Lee of New York, and a class of nurses was graduated.

Insane Hospital Crowded.—Superintendent Orth of the Harrisburg Insane Hospital says that the attention of the courts and the legislature has been repeatedly called to the pitiable crowded condition of the hospital. There are now 213 patients in the hospital beyond its capacity. The overcrowded condition has existed for ten years.

Philadelphia.

Girard Memorial Tablet.—A tablet to the memory of Stephen and Mrs. Girard will be unveiled in November in the Assembly Hall of the Pennsylvania Hospital.

Lectures on Tropical Medicine.—A course of lectures on tropical medicine will be given at the Jefferson Medical College by Capt. Charles F. Kieffer, assistant surgeon U. S. Army. The lectures will be given at 4 p. m. each Monday in the amphitheater of the hospital.

An Unwilling Bather.—John F. Rapp and his wife, Maggie K. Rapp, charge abuse and cruelty against the board of health and bring suit against the city for $25,000 for the alleged forcible removal of the latter from her home, while sick, and compelling her to take a cold disinfectant bath at the Philadelphia Hospital.

Smallpox Continues.—For the week ended October 17, 54 new cases of smallpox were reported to the bureau of health. Within two days, 30 cases were reported. This is the greatest number for one week in the past two years. Eleven new cases were reported for the previous week. The authorities state that the disease will continue so long as people refuse to be vaccinated and there is no compulsory vaccination law.

Faculty Changes.—Dr. George W. Pfromm has been elected clinical professor of applied therapeutics in the Medico-Chirurgical College, and Dr. Hilary N. Christian clinical professor of genito-urinary diseases. Dr. Judson Daland has been nom-

inated by the faculty for election by the board of trustees as professor of clinical medicine. Dr. Mitchell P. Warmuth has been elected demonstrator of operative surgery, and Dr. S. Leon Gans demonstrator and chief of clinic of genito-urinary diseases.

Voluntary Advisory Board.—Drs. William D. Robinson and Charles D. Hart, inspectors of the Eastern State Penitentiary of Pennsylvania, who were appointed as a special committee to obtain the voluntary services of an advisory board of physicians and surgeons, announce the following members of such a board: Surgeon, Dr. Robert G. LeConte; physician, Dr. Judson Daland; ophthalmologist, Dr. George E. de Schweinitz; otologist and laryngologist, Dr. Francis R. Packard; alienist, Dr. Horace Phillips. These will act as consultants with the prison physician.

Wants Medical Inspection in Schools.—Dr. Edward Martin, director of the Department of Public Health and Charities, has asked the board of education to allow a system of medical inspection in all the public schools. It is the plan to have one of the regular city medical inspectors call at each school once a week, and with the coöperation of the principal, to inspect all the children of the school, prescribe treatment when needed, send home those requiring quarantine, receive reports of sickness in the homes of children, and when parents are believed to be ignorant to send a visiting nurse to instruct the mother in the care of the sick child.

Sand May Cause Typhoid.—Regarding the large number of typhoid fever cases occurring in sections of the city supplied with filtered water, Dr. A. Frank Ziegenfus, in an open letter, advances the theory that the infection is from sand dredged or pumped from the Delaware river bed, which the contractors are using in construction of the filter beds. The use of such sand to "purify" Philadelphia's water supply is severely condemned, especially when there are extensive banks of the best surface sand near at hand. From another source attention is called to what are considered grave defects in the new filtration system being constructed, namely, absence of provision for sunlight and aëration.

X-Ray and Light Research.—At the last session of the legislature $25,000 was appropriated to the University of Pennsylvania for a laboratory for *x*-ray research and for Finsen light apparatus. The department will be connected with the University Hospital. It is planned to build a laboratory in connection with the Agnew pavilion. Dr. Henry K. Pancoast, assistant instructor in clinical surgery, and assistant demonstrator of surgery, will have charge of the department. It is the purpose to establish a very complete Finsen light plant, with the prospect of undertaking the first extensive experiments conducted in this country by this method in the treatment of diseases of the skin.

The Moseley Education Commission.—Dr. J. Rose Bradford, professor of medicine, University College, London, and Prof. W. H. Gaskell, fellow of Trinity Hall, Cambridge University, and university lecturer in physiology, were the first members of the Moseley Education Commission to visit Philadelphia. This commission, composed of some of the most distinguished British educators, are visiting this country as the guests of Alfred Moseley, M.P. Their work will include the study of our educational system from the elementary schools to the technical and professional schools and universities. The commission will be tendered a reception by the American Academy of Political and Social Science on the evening of October 24, at which distinguished educators will be present. Dr. Bradford and Professor Gaskell were the guests of Dr. Hobart A. Hare at dinner on October 16. Dr. Bradford purposes visiting New York, Baltimore, Washington, Chicago, Ann Arbor, and Harvard and Yale universities. Dean Charles H. Frazier of the Medical School of the University of Pennsylvania, on October 16, entertained Dr. Bradford and Professor Gaskell at luncheon, at which a number of the faculty were present. The visitors were afterward shown through the various departments of the university.

TEXAS.

Examiners Meet.—The regular State Board of Medical Examiners met at Fort Worth, October 13, and examined 34 candidates for license to practice medicine, and one midwife.

Sanitarium Cornerstone Laid.—On October 11 the cornerstone of Providence Sanitarium, Waco, was laid by the bishop of Galveston with appropriate ceremonies. The institution will cost, with equipment, over $100,000.

Yellow Fever at Laredo.—On October 19, the new yellow fever cases numbered one more than on any day since the outbreak. The official bulletin is as follows: New cases, 36; deaths, 5; total cases to date, 436; total deaths to date, 32.

GENERAL.

Honolulu Hospital Receives Gift.—A former resident of Honolulu, Charles R. Bishop, San Francisco, has given $50,000 to Queen's Hospital, Honolulu. Most of this will be spent in erecting a wing, which is much needed.

FOREIGN.

An outbreak of cholera is reported in Bethlehem, Palestine.

Dowieite in Prison for Cruelty.—On a charge of cruelty to his child, a Dowieite in London was sentenced to a month's imprisonment at hard labor. The little girl broke her collar bone and was compelled to suffer with the break untreated.

Hygienists at Home.—The French Académie de Médecine has always taken the lead in matters of hygiene and its resolutions have commanded the attention of the world. All Paris is smiling now at the discovery that in the hall occupied until recently by the académie each new carpet needed in the century of its existence has been laid on top of its worn and dusty predecessors—ten layers in all.

Antistreptococcus Serum in the Moscow Hospitals.—The Institute of Bacteriology at Moscow has petitioned the municipal authorities for means to defray the expenses so that antistreptococcus serum can be supplied to the hospitals free of charge. The authorities have empowered the physicians in the hospitals to test and report on the serum, and if their report is favorable funds will be appropriated for the desired purpose.

"Archives Latines de Medecine et de Biologie."—This is the title of a new medical monthly recently started by prominent physicians in France, Spain and Italy, to contain articles in the Latin tongues. Each communication will be published in the writer's own language, and be followed by a summary in the two other languages, French, Spanish or Italian as may be. Drs. A. Robin and R. Blanchard of Paris, Cortezo and Ramon y Cajal of Madrid, Maragliano of Genoa and Grassi of Rome are the founders of the new periodical.

LONDON LETTER.

Death of Alexander Bain.

Alexander Bain, the celebrated philosopher, has died at his residence in Aberdeen. Though not a medical man, or even a biologist, his work in the realm of psychology can not be regarded as without importance from the merely professional standpoint. The evolutionary school has largely thrown much of his psychologic work in the shade, but some of it will remain an important and permanent contribution to science. His treatises may be described as "the last word" of the earlier stage of psychology, which proceeded in the main by introspective analysis of the individual mind. The principle of association so fruitfully applied by English philosophers from Hartley to John Stuart Mill received from Bain its fullest development and illustration in every region of mental experience. In insisting on the study of mental facts in connection with their physiologic conditions he was one of the pioneers of newer methods and he laid down the principle of psychophysical parallelism, which most psychologists now employ, at least as a working hypothesis. The stress which he laid on our active experiences of movement and effort was entirely original; and though his theory of a central innervation sense is no longer tenable in the form in which he stated it the investigations to which it gave rise have been an important factor in advancing our knowledge of the subject.

The Drinking of Methylated Spirit in Aberdeen.

In his annual report for 1902 Dr. Matthew Hay draws attention to the growing use in Aberdeen of methylated spirit as a beverage. The government has recently authorized the addition to methylated spirit of a small proportion of petroleum oil (3 to 800). It was thought that such a mixture would be too nauseous to drink. But this modification has failed to effect its purpose. The poorer and more degraded drinkers of Aberdeen take this altered spirit in an increasing degree. It is so cheap that for 2 cents the equivalent of 4 ounces of whisky can be obtained. The extent to which the trade is carried on is shown by the fact that as many as 70 men have been seen to enter a grocer's shop and purchase it for drinking in 2 hours. This spirit produces a state of stupor similar to that of opium poisoning.

Correspondence.

Dead Yet Speaketh.

St. Johnsbury, Vt., Oct. 12, 1903.

To the Editor:—I read my obituary notice, published in your last week's issue, with interest. As Mark Twain said of a similar occurrence: "The report was greatly exaggerated." I was injured in an automobile accident, and received fractures of each femur, dislocation of the left elbow and right shoulder and fractures of the nasal and superior maxillary bones. Aside from these I am all right and am getting on well with them.

John M. Allen.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

MEDICAL BIOGRAPHY.

New York, Oct. 15, 1903.

To the Editor:—After carefully reading your grand editorial in the issue of August 15, on "The Value of Medical Biography to the Medical Student," I ask where I can secure (in English) Sir Michael Foster's Lane Lectures, "Masters of Medicine," and Rene Vallery-Radot's "Life of Pasteur"? S. H. Cassidy.

Ans.—Foster's book on the "History of Physiology," being the Lane Lecture of 1901, is published by the Macmillan Company, New York, price $2.25; "Masters of Medicine," by Sir B. W. Richardson, is published by Longmans, Green & Co., London and New York, price $1.25 per volume; "The Life of Pasteur," in two volumes, is published by McClure, Phillips & Co., New York, price $7.50. Any book house will order them if they are not in stock.

Marriages.

George H. Miller, M.D., to Miss Alice Lawler, both of Chicago, October 7.

Samuel J. McNeill, M.D., to Miss Amy E. Jackson, both of Chicago, September 9.

Clara Meltzer, M.D., to John Auer, M.D., both of New York City, October 1.

William J. Hammond, M.D., Boston, to Miss Edith Lewis, at Baltimore, October 7.

E. Norman Foster, M.D., to Miss Pearl Thomas, both of Pittsburg, Pa., August 20.

Charles W. Pfeiffer, M.D., to Miss Theresa Golm, both of Quincy, Ill., September 30.

W. M. French, M.D., Chicago, to Miss Mabel Shelton of Macon, Mo., September 24.

J. Wesley Graham, M.D., Jackson, Tenn., to Miss Crigler of Saybrook, Ill., October 7.

Van H. Wilcox, M.D., to Miss Margaret Caton, both of Minneapolis, Minn., October 6.

Alvah Childs Remington, M.D., to Anna S. Wilson, both Rochester, N. Y., September 30.

Seeber King, M.D., Lake Butler, Fla., to Miss Agnes V. O. Wilson, at Laurel, Md., October 7.

Philip E. Stockhardt, M.D., Elwood, Ind., to Miss Mabel G. Stout of Louisville, Ky., October 14.

Frederic H. Slayton, M.D., Clifton, Ariz., to Miss Louise Downing of Macomb, Ill., October 6.

A. Aronheim, M.D., Ghent, Norfolk County, Va., to Miss Hilda B. Kline, at Baltimore, October 8.

Roy S. Donaldson, M.D., Maywood, Ill., to Miss Elizabeth Wolfe Giles of Oak Park, Ill., October 12.

William Major, M.D., Aguas Calientes, Mexico, to Miss Maude Meacham of Eureka, Ill., October 7.

Chester A. Miller, M.D., Sharpsburg, Iowa, to Miss Louie Dewees of Fontanelle, Iowa, September 16.

Harlan Page Mills, M.D., Sheridan, Mo., to Miss Maude Edith Benton, at St. Joseph, Mo., October 14.

Albert E. Brennen, M.D., Niagara Falls, N. Y., to Miss Mary McInnes Read, Niagara, September 29.

Henry Krone, Jr., M.D., Hamilton, Ohio, to Miss Grace Janet Seesloth of Richmond, Ind., October 21.

Andrew F. McBride, M.D., Paterson, N. J., to Miss Kathleen Galvin, in New York City, September 29.

Henry E. Haskins, M.D., Kingman, Kan., to Miss Bertha Knappenber of Penaloosa, Kan., September 18.

John W. Osborne, M.D., Rantoul, Ill., to Miss Gertrude Pitsenbarger of Champaign, Ill., September 23.

Robert Bland Grubbs, M.D., U. S. A., San Francisco, to Miss Alice Maude Eagan, at Washington, D.C., September 17.

Albert F. Caldwell, M.D., Shenandoah, Iowa, to Miss Emma Pierce of Boston, Mass., at Clarinda, Iowa, September 26.

Archibald Cameron Nash, M.D., Cleveland, Ohio, to Miss Clara Margaret Huddleston of Hartwell, Ohio, September 30.

Deaths.

JOHN BATES JOHNSON, M.D.

On October 6, Dr. John Bates Johnson, who was the first to receive the honor of being elected vice-president of the American Medical Association, died at his home in St. Louis, aged 86.

He was born at Fairhaven, Mass., April 26, 1817, and was graduated from Harvard University. He then went to Pittsfield, Mass., where he attended Berkshire Medical College and received his medical degree from that institution in 1840. He settled in St. Louis in 1841 and soon attained prominence. Two years after his arrival there he established the first public dispensary west of the Mississippi river and in 1840 he commenced his career as a medical teacher in the Kemper Medical College, which afterward became the Missouri Medical College. In 1850, when the American Medical Association was founded, he was one of its organizers and was made vice-president. He was also one of the founders of the Medical Association of the State of Missouri and served one term as president. In 1854 he was elected to the chair of principles and practice of medicine in the Washington University and con-

JOHN BATES JOHNSON, M.D.

tinued in this position for nearly half a century. At the time of his death he was professor emeritus of this branch.

During the Civil War he was prominent as a member of the United States Sanitary Commission and rendered signal service in raising funds and caring for the sick and wounded soldiers.

Dr. Johnson was one of the most honored and esteemed physicians of St. Louis and was one of the four veterans who, only a few months ago, were tendered a banquet by the medical profession of the city and state. He continued in practice and was in good health until a short time before his death, when acute kidney disease developed, for which an operation was unavailingly performed. He failed rapidly after this and died from uremia.

The St. Louis Medical Society held a special meeting, October 7, at which Dr. Johnson's personality and excellent qualities as a physician and man were eulogized. A committee was appointed to draw up resolutions expressive of his worth and of the society's loss in his death. The society voted to attend the funeral in a body.

David Franklin, M.D. University of New York, 1878, died at his home in New York City, October 6, from septic peritonitis after an operation for appendicitis, aged 48. He was a member of the American Medical, New York State Medical, New York County Medical and Harlem Medical associations and of the Bellevue Hospital Alumni Association. For twenty years he was house physician to the Hebrew Orphan Asylum. At a special meeting of the Harlem Medical Association, October 7, resolutions were unanimously adopted extolling the many noble traits of character of Dr. Franklin, who was once president of the association, and regretting his untimely death.

John W. Hulick, M.D. Medical College of Ohio, Cincinnati, 1882, member of the American Medical Association, American Association of Life Examining Surgeons, Ohio State Medical Society, Clermont and Clark County Medical societies, died at his home in Springfield, Ohio, October 4, from typhoid fever, after an illness of two weeks, aged 45. The Clark County Medical Society at a special meeting, October 5, listened to a brief sketch of Dr. Hulick's life, prepared by Dr. John P. Dugan, and adopted resolutions of regret and regard.

William C. Denman, M.D. Medical College of Ohio, Cincinnati, 1878, a member of the American Medical Association and of the Marion County Medical Society, died at his home in Marion, Ohio, October 1, from Bright's disease, after an illness of a few months, aged 52. The county medical society, at a special meeting called on the day of Dr. Denman's death, decided to attend the funeral in a body, and also adopted suitable resolutions of regret.

James Gamble, M.D. Medical Department of the University of Missouri, St. Louis, 1847, treasurer of the Iowa State Medical Society in 1857 and president in 1870, one of the oldest members of the Scott County Medical Society, assistant surgeon of the Third Iowa Volunteer Infantry in the Civil War, died at his home in Le Claire, Iowa, October 6, after an illness of only twelve hours, aged 82.

Virgil McDavitt, M.D. University of Louisville, 1850, formerly dean of the Quincy (Ill.) Medical College, and during the Civil War, surgeon of the First Alabama Cavalry, died at his home in Quincy, Ill., October 2, from septicemia caused by a prick from an instrument eighteen days before, aged 74. Members of the Adams County Medical Society acted as pallbearers at the funeral.

Sam C. Johnson, M.D. Long Island College Hospital, Brooklyn, N. Y., 1864, formerly president of the Wisconsin State Board of Medical Examiners; a member of the American Medical Association, American Public Health Association, Wisconsin State Medical Society, and the Inter-County Medical Society, died suddenly at his home in Hudson, Wis., October 17, from heart disease.

David Rector McKinney, M.D. Medical College of Indiana, Indianapolis, 1878, of Banquo, Ind., an old practitioner of Champaign County, Ill., and some-time president of the county medical society, who was injured by falling from a train near Fithian, September 17, died as a result of his injuries at the home of his son in Gifford, Ill., September 29, aged 66.

William Danderson Wood, M.D. Castleton (Vt.) Medical College, 1854, one of the organizers and for several terms president of the Queen's County Medical Society, and surgeon of the Eighty-ninth New York Volunteer Infantry in the Civil War, died at his home in Jamaica, L. I., October 4, aged 82.

Cornelius Shepherd, M.D. University of Pennsylvania, Philadelphia, 1861, a member of the American Medical Association, died at his home in Trenton, N. J., October 7, after a lingering illness, aged 66. He was active in establishing the present school system in New Jersey.

Joseph Hinson Mellichamp, M.D. Medical College of the State of South Carolina, Charleston, 1852, of Bluffton, S. C., surgeon in the confederate service during the Civil War, and an eminent botanist, died on James Island, S. C., October 3, after a long illness, aged 74.

Albert S. Amerman, M.D. University of Michigan, Ann Arbor, 1871, of Rockford, S. Dak., twice a representative in the legislature, a pioneer physician and gold-seeker in the Black Hills, died at Rapid City, S. Dak., October 6, from dropsy, after a long illness, aged 54.

William Johnson Dale, M.D. Harvard University Medical School, Boston, 1840, for 21 years surgeon-general of Massachusetts, and acting medical director U. S. Army during the Civil War, died at his home in North Andover, Mass., October 7, aged 88.

George Landerkin, M.D. University of the Victoria College, Cobourg, Ont., 1862, died at his home in Hanover, Ont., October 4, aged 64. He was elected to the House of Commons in 1873, and subsequently occupied a seat in the house from 1882 until 1896.

Chas. F. Goodrich, M.D. St. Louis Medical College, 1866, assistant surgeon in the Ninth Missouri Volunteer Cavalry and a member of the American Medical Association, died at his home in New Haven, Mo., September 25, from apoplexy, aged 66.

James Davis Gardiner, M.D. Columbus (Ohio) Medical College, 1879, one of the oldest practitioners of Illinois, died at the home of his daughter in Farmer City, Ill., from paralysis, after an invalidism of four years, September 28, aged 83.

Edward E. Stonestreet, M.D. University of Maryland, Baltimore, 1852, secretary of the Montgomery County Board of Health, died, October 9, from heart disease at his home in Rockville, Md., where he had practiced for 51 years, aged 73.

Benjamin F. Rivers, M.D. Howard University, Washington, D. C., 1902, house physician of the Charleston Hospital and Training School for Colored Nurses, died at the home of his father on James Island, S. C., September 25.

Charles Blackwell Sweeting, M.D. London College Hospital, 1867, of Key West, Fla., a member of the American Medical and the Florida Medical associations, died in Brooklyn, N. Y., October 4, after a lingering illness, aged 58.

John Polson, M.D., a member of the American Medical Association, Medical Association of the State of Missouri and Linn County Medical Society, died at his home in Laclede, Mo., October 13, from typhoid fever, aged 61.

Edwin N. McPheeters, M.D. Tulane University, New Orleans, 1903, interne at the Natchez (Miss.) City Hospital, died at the hospital, October 2, a short time after an operation for appendicitis, aged 21.

George W. Bowen, M.D. University of Pennsylvania, Philadelphia, 1872, a member of the Philadelphia County Medical Society, died at his home in Philadelphia, September 30, aged 56.

Lyman M. Willard, M.D. University of Pennsylvania, Philadelphia, 1870, was found dead in bed, September 29, at his home in Loomis, Wash., with a bottle of chloroform in his hand.

Wilson W. Stroup, M.D. University of Pennsylvania, Philadelphia, 1874, committed suicide by shooting himself with a revolver at his home in Harrisburg, September 30, aged 54.

Charles G. Bowers, M.D. Medico-Chirurgical College, Philadelphia, 1903, of Brooklyn, N. Y., fell from a train near Jersey City, September 26, and was drowned, aged 25.

Thomas V. Gifford, M.D. Hygeio-Therapeutic College of New York, 1863, a noted opponent of vaccination, died at his home in Kokomo, Ind., September 25, aged 72.

J. Walter Burch, M.D. University of Maryland School of Medicine, 1903, died from obstruction of the bowels, in Baltimore, October 2, aged 26.

William A. Evans, M.D. New York University, 1859, died October 8, from gunshot wounds accidentally received, at his home in Aberdeen, Miss.

Michael C. Kreitzer, M.D. Jefferson Medical College, Philadelphia, 1850, died from apoplexy at his home in Philadelphia, September 25, aged 77.

John T. Slaughter, Jr., M.D. Atlanta Medical College, 1879, of Villa Rica, died at Grady Hospital, Atlanta, October 3, from appendicitis, aged 51.

W. H. Russell, M.D., of Providence, R. I., died recently and was buried September 21, the pallbearers being brother physicians of Providence.

Lyman N. Mixer, M.D., an eclectic physician of Hastings, Mich., died, September 22, from paralysis, after an illness of one week, aged 75.

John R. Goodale, M.D. Eclectic Medical College of the City of New York, 1872, died at his home in Oakland, Cal., September 26, aged 67.

Franz F. A. Hoogen, M.D. Missouri Medical College, St. Louis, 1886, of St. Louis, died at his winter home in Helwan, Egypt, October 7.

Armand Derivaux, M.D. Faculty of Medicine, Paris, France, 1876, a veteran of the Franco-Prussian War, died at his home in St. Louis recently.

Jesse Taylor, M.D. Eclectic Medical Institute, Cincinnati, 1897, died at his home in Vermont, Ill., October 2, after a short illness, aged 30.

Andrew Jackson McIntyre, M.D. University of Michigan, Ann Arbor, died from pneumonia at his home in Galatia, Ill., October 2.

J. Chester Pratt, M.D. Eclectic Medical College of the State of New York, 1891, died at Springfield, Mass., October 5, aged 36.

Dominick F. Harang, M.D. Tulane Medical College, New Orleans, 1901, died at his home in New Orleans, October 5, aged 25.

James M. Brydon, M.D. Medical College of Indiana, Indianapolis, 1875, died at his home in Chicago, September 29, aged 59.

John D. Key, M.D. Bellevue Hospital Medical College, New York, 1885, died at Halfmoon Bay, Cal., September 24, aged 40.

James Nixon Butt, M.D. University of Pennsylvania, Philadelphia, 1855, died at his home in Orlando, Fla., September 29.

George K. Elder, M.D., of Kansas City, Mo., died at Toledo, Ohio, October 1, from dropsy complicated with asthma, aged 50.

James W. Akers, M.D., Jefferson Medical College, Philadelphia, 1876, died at his home in Curran, Ill., September 28.

A. M. Jackman, M.D. University of Louisville, 1874, died at his home near Kendall, Ky., October 3, aged 64.

William G. Montgomery, M.D., of Minden, Ont., died at Gorrie, Ont., September 8, aged 29.

George W. Henderson, M.D., died at his home in Waynesville, Ohio, September 27.

W. Frank Park, M.D., died at his home in Tracy City, Tenn., September 30.

Deaths Abroad.

Theophile Roussel, M.D., died at his country home at Mende, September 27, aged 87. He was venerated throughout France for his active and enlightened philanthropy, and especially as the author of the laws for the protection of children, nurslings boarded out, factory children and those abandoned and ill treated. He served for many years as senator from Lozère and on important committees. His eightieth birthday was the occasion of an ovation from the authorities and the public in general, the government presenting him with a gold medal. His published works on medical and hygienic subjects are numerous, his "Public and Private Charities" being the standard reference book on this subject.

A. Rollett, M.D., one of the most prominent physiologists of his day, died at Graz, October 1, aged 70.——**E. Pflueger, M.D.**, professor of ophthalmology at Berne, died September 28, aged 57.——**A. Regnard, M.D.**, "inspecteur général des services administratifs" at Paris, died September 28, aged 77.——**E. Boisseau, M.D.**, chief of the army sanitary service of France, died at Paris, September 25.

H. R. Pott, M.D., died at Halle, September 25, aged 59. He was born and graduated at Halle and has served there as professor of children's diseases since 1883. He was a frequent contributor to the medical press on subjects connected with internal medicine and pediatries.

P. Goetsch, M.D., died at Slawentzitz, September 24. His report of the remarkable success obtained at the sanatorium in his charge by treatment of tuberculosis with long continued, minute doses of tuberculin, attracted much attention three years ago.

R. Landau, M.D., died at Nuremberg, September 21, aged 39. His name is well known by his numerous contributions to the medical press and his works on the history of medicine, especially his "History of Jewish Physicians."

F. Wuerth, M.D., died at Freiburg in September, aged 98. He had long been the oldest practicing physician in Germany, his medical degree dating from 1828.

Miscellany.

A Medical Museum.—Rush Medical College, Chicago, has established a museum in which will be preserved and exhibited permanently objects of interest and value in the history of medicine. Especial attention will be given obsolete instruments and appliances for the diagnosis and treatment of disease. Many physicians and others have instruments that perhaps even a short time ago were in use, but which have been laid away for more recent inventions; these are of historical value. Medicine in the United States has so brief a history that it should not be difficult to represent in this museum its complete development in the instruments and appliances that have come and gone, that have been of great value, but have given place to better inventions as the art has progressed. The late Professor Fenger bequeathed his own instruments to this museum, and it was the wish of this thoughtful man that his gift should be but the foundation for a collection that would show the development of the art he loved and for which he did so much. Rush Medical College has set aside a commodious room in the newly-opened Senn Hall for the permanent use of this museum. Gifts will be inscribed with the name of the donor, and any remarks as to their history, original owner, user, etc., that may increase their interest. All other objects that have any interesting relation to the history of medicine or to renowned physicians will be given place, such as original manuscripts, autograph letters, portraits, etc. Information may be had by addressing Rush Medical College, Chicago.

[Signed] DR. F. HENROTIN.
(Class of 1868.)

State Boards of Registration.

COMING EXAMINATIONS.

Louisiana State Board of Medical Examiners, Tulane Medical College Bldg., New Orleans, Oct. 26-27.

State Board of Examiners of Alabama, Montgomery, Nov. 1-10.

Oklahoma Medical Examining Board, Enid, Nov. 10.

Committee of the Connecticut Medical Society, City Hall, New Haven, Nov. 10.

Board of Registration in Medicine of Massachusetts, State House, Boston, Nov. 10-11.

State Board of Health of West Virginia, Point Pleasant, Nov. 10, 11, 12.

Nebraska State Board of Health, Lincoln, Nov. 11.

Board of Registration of Medicine of Maine, Augusta, Nov. 11.

District of Columbia Report.—The Board of Medical Supervisors of the District of Columbia, in their sixth annual report, say that they have decided, after long consideration of the subject, that reciprocity is impossible without an amendment of the law under which they operate. They announce plans for the prosecution of those who are practicing criminally, and those who are liable to a revocation of license for other reasons.

Ohio Reciprocity.—The State Board of Medical Registration and Examination of Ohio adopted the following resolution at its regular meeting, October 6, 1903:

The Ohio State Board of Medical Registration and Examination will dispense with the examination of a candidate presenting a license from another state board, or from the Board of Examiners of the District of Columbia, issued after an examination on which a general average of 75 per cent. was obtained, on payment of the fee, $50, required by law; provided, the applicant was, at the time of such examination, the holder of a diploma from a medical college recognized as in good standing by the state board of Ohio, and provided that the applicant has complied in all other particulars with the laws of Ohio governing the practice of medicine and surgery and the rules of the Ohio State Board of Medical Registration and Examination, and provided that the state board issuing such license will, in like manner, accept the license issued by this board.

Book Notice.

A TEXT-BOOK OF OBSTETRICS. By J. Clarence Webster, M.D. Edin., F.R.C.P.E., F.R.S.E., Professor of Obstetrics and Gynecology, Rush Medical College, in Affiliation with the University of Chicago. With 383 Illustrations; 23 in Colors. Cloth. Pp. 761. Price, $5.00 Philadelphia, New York, London: W. B. Saunders & Co. 1903.

Webster has adopted a different arrangement from that usually found in works on obstetrics. He first considers normal pregnancy, normal labor, and the normal puerperium, then their pathology in the same order, followed by operative obstetrics. In part one, consisting of seven chapters, are considered the anatomy and physiology of pregnancy, bacteriology of the vagina, diagnosis, length of gestation, multiple pregnancy, false pregnancy and management of pregnancy. The first chapter on the anatomy and physiology of pregnancy is the most important from the scientific viewpoint. The theme is one on which the author is especially qualified to write, as it is one to which he has devoted much time in research and investigation. Naturally, therefore, we might expect to find all the latest scientific views and most recent established facts regarding placentation, etc. The author has not only given us these, but being thoroughly master of the subject, he is able to present the matter clearly and lucidly and in such a manner that the ordinary student can easily grasp and master it. This is especially noticeable in the discussion of the anatomy and physiology of the fetus. In the chapter on the bacteriology of the vagina in pregnancy is given, in brief, the results of the various experimental investigations and examinations of the vaginal secretions, and the author concludes that douching for prophylactic purposes either before or after confinement is unnecessary, unless there has been exposure to contamination. The subjects of diagnosis of pregnancy, length of gestation, and management of normal labor are considered fully and in every detail. In the five chapters of part two are considered the clinical phenomena, anatomy and physiology, and conduct and management of normal labor, together with asepsis and antisepsis and anesthesia. The chapter on the anatomy and physiology of normal labor is accompanied with illustrations that are especially to be commended, many of them being taken from frozen sections, and all being true to nature. As might be expected, the author is very insistent and emphatic regarding the value of asepsis in labor; but not too much so. He is not a faddist and his recommendations and suggestions are practical and can easily be carried out by every practitioner. The three chapters in part three are devoted to the management of the puerperium and the care of the new-born child. In part four—fifteen chapters—the diseased conditions complicating pregnancy are considered. Part five, composed of five chapters, is devoted to the various complications of labor; part six—three chapters—to the pathology of the puerperium, and part seven—six chapters—to operative work. Every subject is thoroughly covered and no detail, so far as we can find, has been omitted. The author recognized that thorough knowledge of the anatomic and pathologic changes that occur in pregnancy, in labor and in the puerperium is a necessary basis for a clear understanding of the various complications and conditions that are to be met in obstetric work, and consequently more than usual attention is given to these subjects. The work represents the most modern views—those that are based on proven facts; it is scientific in the best sense of the word, and at the same time it is practical. It is written for the scientific student and also for the general practitioner who does the major portion of obstetric work. In considering the management of complications and the treatment of conditions the directions are given with clearness and exactitude, and only those methods and remedies are recommended that have been proven. The illustrations are especially to be commended. While we miss many of the old reliable cuts that have done service for so long and in so many books, yet in their places are those more in accord—artistically and for practical use—with present-day knowledge and requirements. As a whole, the book represents as much of a step forward in the obstetric literature of our day as did the classic work of Lusk nearly a quarter of a century ago.

Medical Organization.

California.

SHASTA COUNTY MEDICAL ASSOCIATION.—Physicians of the county met at Redding, September 21, with Dr. Andrew W. Morton, San Francisco, trustee of the state society, and organized a county society to be auxiliary to the state organization. Dr. Olin J. Lawry was elected temporary president, and Dr. R. F. Wallace temporary secretary, both of Redding; Drs. R. F. Wallace, John M. Read and Joshua T. Rohn, all of Redding, were appointed a committee to complete the organization and to draft a constitution and by-laws.

Indian Territory.

NORTHERN DISTRICT MEDICAL SOCIETY.—The physicians of the Northern District of the Indian Territory have organized with the following officers: Dr. Benjamin F. Fortner, Vinita, president; Drs. William T. Tilly, Pryor Creek, and Frank L. Wormington, Miami, vice-presidents, and Dr. Robert H. Harper, Afton, secretary and treasurer.

Indiana.

VIGO COUNTY MEDICAL SOCIETY.—Dr. Myron A. Boor, Terre Haute, councilor for the Fifth District, met the Vigo County Medical Society at Terre Haute, October 1, and explained the plan of reorganization recommended by the American Medical Association. The society then adopted the standard constitution and by-laws.

FOUNTAIN COUNTY MEDICAL SOCIETY.—On October 1 this society, one of the oldest in the state, met at Covington and reorganized, adopting the standard constitution and by-laws. Dr. Paul J. Bareus, Crawfordsville, councilor for the Ninth District, was present and aided in the reorganization. Dr. Charles J. Wert, Kingman, was elected president, and Dr. George Rowland, Covington, secretary-treasurer.

Iowa.

MUSCATINE COUNTY MEDICAL SOCIETY.—This society made a complete reorganization, October 8. The charter membership was 20. Dr. Henry M. Dean was made temporary chairman, and Dr. Thomas F. Beveridge temporary secretary, both of Muscatine. The temporary organization was made permanent.

SAC COUNTY MEDICAL SOCIETY.—Physicians of the county met at Sac City, October 6, and organized this society. The following officers were elected: President, Dr. Thomas Farquhar, Early; vice-president, Dr. William Y. Herrick, Lytton; secretary, Dr. Frank H. McCray, Schaller; treasurer, John H. Stalford, Sac City, and censors, Drs. Zachary Fuller, Sac City, John W. Graham, Early, and Andrew T. Brenton, Sac City.

WASHINGTON COUNTY MEDICAL SOCIETY.—The annual meeting was held in Washington, October 8. Dr. Charles E. Ruth, Keokuk, councilor for the First District, was present and explained the plan of reorganization, and the society adopted a constitution and by-laws in accordance therewith. The following officers were elected: Dr. George W. Hay, Washington, president; Dr. Charles W. McLaughlin, Crawfordsville, vice-president; Dr. Clyde A. Boice, Washington, secretary and treasurer; Dr. Edward R. Jenkins, delegate to Iowa State Medical Society, and Drs. William E. Fordyce, Ainsworth, Emmett T. Wickham and J. C. Boice, Washington, censors.

Louisiana.

WEST BATON ROUGE PARISH MEDICAL SOCIETY.—On October 1, six of the seven available physicians of the parish met at Devall, and organized a parish society with Dr. Franklin H. Carruth, Lobdell, president; Dr. James O. St. Dizier, Walls, vice-president, and Dr. H. Guy Riche, Devall, secretary-treasurer.

EAST FELICIANA PARISH MEDICAL SOCIETY.—Physicians of the parish met in Wilson, October 3, and organized, with the assistance of Dr. John M. Barrier, president of the state society. Dr. S. L. Singletary, Wilson, was elected president; Dr. Aquippa Gayden, Norwood, vice-president, and Dr. E. C. McKowen, Jackson, secretary and treasurer.

EAST BATON ROUGE PARISH MEDICAL ASSOCIATION.—Dr. J. M. Barrier, Delhi, president of the Louisiana State Medical Society, met the physicians of the parish at Baton Rouge, October 1, and organized a parish society with 12 members. The following officers were elected: Dr. James W. Dupree, Baton Rouge, president; Dr. George W. Sitman, Burtville, vice-president, and Dr. Charles McVea, Baton Rouge, secretary and treasurer.

VERMILION PARISH MEDICAL SOCIETY.—Dr. Milton R. Cushman, Abbeville, was chairman, and Dr. Clarence J. Edwards, Abbeville, secretary, of an informal meeting of physicians of

the parish, October 3, at Abbeville, for the purpose of taking steps to reorganize in accordance with the plan proposed by the American Medical Association. It was resolved not to go into permanent organization until all the reputable physicians of the parish had been afforded an opportunity to participate. The meeting then adjourned until October 15.

North Carolina.

Cleveland County Medical Society.—Dr. Edward C. Register, Charlotte, organized a county medical society at Shelby, September 12.

Davie County Medical Society.—Dr. Thomas E. Anderson, Statesville, councilor for the Fourth District, met physicians of Davie County recently and organized a county society with Dr. M. D. Kimbrough, Mocksville, president; Dr. Robert L. Rierson, Cooleemee, vice-president, and Dr. W. C. Martin, Mocksville, secretary and treasurer.

Duplin County Medical Society.—Dr. Frank H. Russell, Wilmington, at Warsaw, October 2, organized a county society with the following officers: Dr. John M. Faison, Faison, president; Dr. A. N. Smith,, Magnolia, vice-president; Dr. Benjamin R. Graham, Wallace, secretary and treasurer, and Drs. J. W. Carroll, Wallace, James M. Williams, Warsaw, and Albert F. Williams, Kenansville,, censors.

Columbus County Medical Society.—Dr. Frank H. Russell, Wilmington, on September 29, organized a county society whose membership is said to include every physician in the county. The following officers were elected: President, Dr. N. A. Thompson, Whiteville; vice-president, Dr. Samuel M. Withers, Chadbourn; secretary and treasurer, Dr. J. Clegg Hall, Boardman, censors, Drs. John M. McGougan, Cerro Gordo, David B. Jordan, Cronly, and Henry B. Maxwell, Whiteville.

Mecklenburg County Medical Society.—This society was organized at Charlotte, October 7, with an initial membership of 41, under the standard constitution. The following officers were elected: Dr. Harry Q. Alexander, Davenport, president; Dr. Annie L. Alexander, Charlotte, vice-president; Dr. Parkes M. King, Concord, secretary and treasurer; Drs. Walter P. Craven, Charlotte; I. Wellington Faison, Charlotte, and Theodore F. Pharr, Harrisburg, censors, and Drs. Edward C. Register, Calvin S. McLaughlin and F. O. Hawley, all of Charlotte, committee on public health and legislation.

North Dakota.

Sixth Judicial District Medical Society.—The physicians of the Sixth Judicial District organized at Bismarck with the following officers: Dr. Francis R. Smyth, Bismarck, president; Dr. G. E. Chamberlain, Bismarck, vice-president; Dr. Frederick B. Strauss, Glenullin, secretary-treasurer, and Drs. George A. Perkins, Dickinson, Gilbert B. Furness, Mandan, and Nels O. Ramstad, Bismarck, censors. A committee was appointed to draw up a constitution and by-laws conforming to the recommendations of the American Medical Association.

Ohio.

Henry County Medical Society.—On October 7, Dr. Julius H. Jacobson, Toledo, councilor for the Fourth District, organized at Napoleon a county society, with the following officers: President, Dr. Eugene B. Harrison, Napoleon; vice-presidents, Drs. Harry P. Haag, Liberty, and Ora L. Norris, Deshler; secretary and treasurer, D. Alfred E. H. Mearker, Napoleon, and censors, Drs. John Bloomfield, Napoleon, Samuel E. Miller, Florida, and James D. Archer, Holgate.

Texas.

Parker County Medical Association.—Dr. Charles E. Cantrell, Greenville, councilor for the Fourteenth (North Texas) District, organized this association at Weatherford, October 5.

Fannin County Medical Association.—Physicians of the county met at Bonham, October 5, and organized with Dr. John M. Neel, president; Dr. Carey A. Gray, vice-president, and Dr. Alvis B. Kennedy, secretary and treasurer, all of Bonham.

Bell County Medical Society.—On October 3, 39 physicians of Bell County met at Belton and organized on the standard plan with the following officers: Dr. Jacob M. Frazier, Belton, president; Dr. J. H. Payne, Holland, vice-president, and Dr. John M. McCutchan, Temple, secretary and treasurer.

Big Springs District Medical Association.—This has been organized at Colorado with the following officers: Dr. William H. Morrow, Dunn, Scurry County, president; Dr. Preston C. Coleman, councilor for the Second District, Colorado, vice-president, and Dr. Willis R. Smith, Colorado, secretary and treasurer.

Wisconsin.

Price County Medical Society.—Dr. John M. Dodd, Ashland, councilor for the Tenth District, organized a county society at Phillips.

Monroe County Medical Society.—Physicians of the county met at Sparta, October 6, and organized under the standard constitution. The following officers were elected: President, Dr. George R. Vincent, Tomah; vice-president, Dr. Crawford E. Phillips, Wilton; secretary and treasurer, Dr. Carl M. Beebe, Sparta; delegate to the Wisconsin State Medical Society, Dr. Wilbur T. Sarles, Sparta, and censors, Drs. Jacob J. Simonson, Tomah, Cornelius H. Cremer, Cashton, and Fred P. Stiles, Sparta.

Society Proceedings.

COMING MEETINGS.

Congress of State and Provincial Boards of Health of North America, Baltimore, Oct. 23-24.

American Public Health Association, Washington, D. C., Oct. 26-30.

Hawaiian Territorial Medical Society, Honolulu, Nov. 7.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.

Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 15.

Western Surgical and Gynecological Association, Denver, Dec. 28-29.

PENNSYLVANIA STATE MEDICAL SOCIETY.

Fifty-third Annual Meeting, held at York, Sept. 22 to 24, 1903.

(*Concluded from page 982.*)

Is Registration and Disinfection a Successful Method of Combating Pulmonary Consumption?

Dr. Thomas J. Mays of Philadelphia read this paper at the second session of Section A, Wednesday afternoon, September 23. He gave an elaborate array of statistics and concluded that thus far registration and disinfection do not appear to be a success in combating consumption.

Dr. Lawrence F. Flick, Philadelphia, in speaking on "The Prevention of Tuberculosis," called attention to the fact that many deaths formerly accorded to bronchitis, inanition, etc., are now recorded strictly under the tables they should be, because there is a clear diagnosis of tuberculosis and not of pneumonia or of bronchitis.

The Specific Treatment of Tuberculosis.

Dr. Mazyck R. Ravenel, Philadelphia, reviewed the attempts made to discover a specific against tuberculosis. He believes that past results justify the strongest hope that the immunization of man against tubercle bacillus may be realized in the near future.

Trauma and Phthisis.

Dr. William T. English, Pittsburg, read a paper on "Trauma as an Etiologic Factor in Phthisis Pulmonalis." He believes that passive predisposition is often rendered active by the intervention of traumatism, and states that injury awaits the thorax and contained organs from the period of formation *in utero* throughout all independent existence, and that resulting traumatism has the power to produce phthisis pulmonalis, or to make more favorable the soil for tubercular deposit. The author emphatically declares that it is unfair to withhold sick benefits and remuneration for accident from those who develop phthisis pulmonalis after injury. Out of 128 cases in injury followed by traumatic pneumonia the writer finds that about 63 per cent. were associated with fracture. The conclusion seems justified that over 48 per cent. of those recovering from the immediate results of the injury and pneumonia developed pulmonary phthisis.

Discussion on Tuberculosis.

Dr. Lawrence F. Flick said he thought it would be a little bit dangerous in the sense of equity to conclude that because a person has developed tuberculosis which has been preceded by traumatism that he is entitled for damages in a suit for damages. He is of the opinion that there has been previously the implantation of the disease. He also thought that the

statistical tables presented by Dr. Mays were exceedingly misleading. The mere fact of an increase in the death rate of tuberculosis means nothing unless all other factors are excluded.

DR. M. V. BALL inquired whether Dr. Flick would advise the establishment of sanatoria in a county such as his, one of the very dampest, and thus deprive the patients of seeking a more favorable climate.

DR. ALEXANDER R. CRAIG said that in sanatoria under the management of the Massachusetts State Board of Health, in spite of the fact that the country is damp and the land is somewhat low, the results shown in the work are extremely gratifying. He assumed that there were many in Warren County who could not get out of their own county, and that it was better to give them the benefit of a sanatorium.

DR. A. C. WENTZ, Hanover, said that the majority of the profession must first learn to recognize a tubercle bacillus before they can decide when a man shall go to such and such a place for his health.

DR. MAYS said that he believed that no more blunders occurred twenty years ago than occur now in physical diagnosis of lung diseases. Notwithstanding that New York has followed the methods of disinfection and registration, Dr. Mays stated his statistics show that in New York the death rate from pneumonia has been the highest in the last ten years of any city or locality. The death rate of phthisis, consumption and tuberculosis has diminished in New Jersey and in Washington in the last fifteen or twenty years, but in these places there has not been registration or disinfection.

DR. FLICK called attention to the death rate of pneumonia in children referred to by Dr. Mays, and stated that ten or fifteen years ago nearly all deaths from lung disease in children were recorded as bronchitis, while now they are known as pneumonia. This is also true concerning the death rate of old age. This has been the cause of the increase of the death rate of pneumonia.

Committee on School Text-Books.

The report of the committee appointed to examine school text-books, which is given above (page 925, October 10) was, after much discussion, laid on the table and a new committee of five was appointed to continue the work of examination and scientific comment on the text-books of physiology and hygiene used in the public schools of Pennsylvania.

Family Periodic Paralysis.

DR. GEORGE F. HOLTZAPPLE, York, read a paper by this title at the third session of Section A, Thursday morning, September 24. He gave a history of the affection as he had seen it in a family extending through four generations. Of the family of which the author writes a number have died in an attack. The cases were minutely described, and their characteristic symptoms and clinical phenomena correspond to those of cases previously observed by European and American investigators. The author believes that a postmortem would doubtless reveal much explanatory of the pathology. Personally he regards the condition one of vasomotor neurosis affecting the blood supply to the anterior horns which are almost wholly supplied by the anterior spinal artery. Believing that the attacks of hemicrania and paralysis in this family have a common cause and assuming that both conditions are a vasomotor neurosis, large doses of bromids with caffein were used, repeated in one or two hours if necessary. Prophylaxis he regards as an important matter in some cases. With a view to making a decided impression on the nervous system only large doses of bromids have been used.

Case of Cerebral Thrombosis with a Skiagraph Showing the Area of Softening.

DRS. CHARLES W. BURR and G. E. PFAHLER, Philadelphia, described the case of a woman 67 years of age who had had a stroke 30 years before, resulting in a right-sided hemiplegia and aphasia. Although she had complete motor aphasia, word blindness and agraphia, word deafness was not complete. The auditory speech center, however, was completely destroyed. There was some word deafness. Dr. Pfahler had made a skiagraph postmortem, having replaced the brain for the purpose. The picture showed many of the normal contents of the skull and the area of softening. Stress was laid on the fact that in interpreting skiagraphs little dependence could be placed on the results, unless the normal structures came out well. If they failed to be shown appearances seemingly abnormal might be so or not. The value of skiagraphy in the differential diagnosis of hemorrhage and thrombosis from hemiplegia occurring in uremia without any gross cerebral lesion, was considered.

DISCUSSION.

DR. PFAHLER said that Dr. Charles K. Mills had reported three cases of brain tumor in which the skiagraphic report was confirmed by operation. One was of unusual interest from the fact that it was a gumma and was only about half an inch in thickness. The shadow shown corresponded exactly in size, shape and location with the gumma removed.

(*To be continued.*)

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-ninth Annual Meeting, held at Memphis, Oct. 7 to 9, 1903.

(*Continued from page 982.*)

This meeting was held under the presidency of Dr. Edwin Walker, Evansville, Ind. His president's address on the conduct of the practice of the general practitioner will be published in THE JOURNAL. The meeting was a great success from a scientific standpoint, although the attendance was no larger than usual. The papers were of unusual merit and were of practical value to the practitioner, establishing a standard perhaps higher than that of any previous meeting. The long discussions on the much-fought-over points in pneumonia and appendicitis treatment were lacking and the other papers were actively discussed. The social side of the meeting included an old southern barbecue, a reception and ball, a trolley party and other events and made this feature of the meeting one of unusual pleasure to all.

The Decision to Operate.

DR. AP MORGAN CARTLEDGE, Louisville, Ky., in the address in surgery, said that the physician or surgeon who decides that an operation should be performed should be keenly alive to the alarm and perturbation his announcement would cause to both patient and friends. Therefore, he should be prepared to make such announcement with the greatest clearness and candor, mingled with as much encouragement and hope as the condition would justify. He sounded a note of warning against the too common practice of treating surgical operations as trivial affairs, free from danger and pain.

The following four papers, which were read, will be published in THE JOURNAL: "The Causes of Occasional Failure of Operation to Cure Gallstone Disease," by Dr. W. J. Mayo, Rochester, Minn.; "Penetrating and Perforating Gunshot and Stab Wounds of the Abdomen," by Dr. John Young Brown, St. Louis; "The Importance of Medical Organization in Securing and Enforcing Medical Laws," by Dr. T. J. Happel, Trenton, Tenn.; and "Treatment of Tubercular Joints," by Dr. David C. Peyton, Jeffersonville, Ind.

The Prevention of Heart Disease.

This was the subject of the address in medicine by Dr. Robert H. Babcock, Chicago. He regarded the removal of all chronically diseased tonsils as of the utmost importance in all persons who had had once an attack of inflammatory rheumatism, whether the heart had been damaged or not. The physician should guard against the results of syphilis, gonorrhea, pneumonia, chorea, scarlatina, influenza, diphtheria, overstrains and toxic affections, constantly bearing in mind the liability to cardiac mischief.

Medical Organization.

DR. J. N. MCCORMACK, Bowling Green, Ky., stated that it was only a question of time when every state society in the Union would adopt the plan of reorganization of the American Medical Association. The results thus far accomplished are

very encouraging. Within the last two years progress has been very rapid in many states. For instance, in Michigan the membership of the state society within one or two years has increased from 490 to almost 2,100 members; in Kentucky from less than 400 to nearly 1,600. Dr. McCormack urged physicians to establish pleasant relations with one another. With this idea in view every physician in the United States should begin to do good, and soon personal bickerings would be at an end.

Relation of the Medical Department of the United States Army to the Profession.

Major W. C. Borden, U. S. A., Washington, D. C., delivered an address on this subject. The medical department of the United States Army is recruited from all parts of the United States, and is, therefore, in a way representative of the medical profession of the country. Men from all prominent medical schools and hospitals are found in its ranks. The standing and efficiency of the medical department are of importance to the medical profession, not only as it is in part representative of that profession, but also from the important relation which it bears to the efficiency of the Army as a whole, and, therefore, the interests of the nation at large.

The ranking of medical officers below that of officers of other staff departments is distinctly derogatory to the dignity of the profession, and the profession at large should see that the medical department of the Army receives due recognition.

Only by mutual assistance and support can the profession attain its highest end. This is true of the various professional societies and of the medical departments of the Navy, the Army and the Public Health and Marine-Hospital Service.

In the past the relationship between the officers of the medical department of the Army and the profession at large has always been close, and thereby the officers of the medical department have kept in touch with the great advances in medicine and surgery which the civil practitioner in time of peace has the greatest opportunity to practice. In return, in time of war the civil practitioner called into the military service has to look to his brother in medicine, who has spent his life in the military service, for those details of medico-military work on which the efficiency of an army depends, and by which sickness and suffering may be prevented, or alleviated under war conditions. At all times, therefore, greatest good to the greatest number and the best interests of the nation demand that the most cordial relationship, association and unity of endeavor obtain between the medical department of the Army and the profession at large. With this in mind, community of interest, mutual support, and work toward the common good of our fellows and our country will increase.

Hypodermatic Use of Mercury in Syphilis.

Dr. S. P. Collings, Hot Springs, Ark., said that the use of this method should be largely confined to cases in which there was a necessity for the patient to be brought rapidly under the influence of mercury.

Specialism in Its Modern Significance.

Dr. Albert B. Hale, Chicago, said that no real dividing line separates the branches of medicine, but modern specialism means time to devote to the delicate technic of diagnosis and of treatment. If these functions are not recognized for the patient's good, but if every practitioner accepts cases on which to practice, even when not equipped, the advance of true specialism is discouraged.

The Early Diagnosis of Mental Diseases.

Dr. C. B. Burr, Flint, Mich., outlined the differential diagnosis of many conditions. Self-deception on the part of the physician or inaccuracy in diagnosis leads to improper methods of management. The prescription of travel often made for neurasthenics was deplored and hospital care was advised.

What a General Practitioner Should Do in the Early Stages of Mental Disease.

Dr. Brooks F. Beebe, Cincinnati, said that the great progress in the treatment of mental diseases is a result of the recognition that psychology rests on physiologic bases, and metaphysical theories no longer have weight. In the treatment of mental diseases the intelligent physician should proceed in the same way as in treating other affections.

Masked Epilepsy.

Dr. W. B. Fletcher, Indianapolis, said this disease, usually unrecognized until it had progressed to a degree dangerous alike to the patient and those about him, presented one of the most intricate medicolegal questions. Little is known of the pathology. Among adults it is usually caused by alcoholic, syphilitic and autotoxic conditions. Treatment should begin with the mildest symptoms and war be waged on the vicious constitutional tendencies.

Local Lesions and Treatment of Amebic Dysentery.

Dr. James P. Tuttle, New York City, said that the value of flushing the bowel with cold water had been repeatedly proven. Flushings were given three or four times a day from a fountain syringe, in winter using water direct from a hydrant, in summer adding a little ice. At least one douche a day was continued for eight weeks. Treatment of rectal ulcers should be carried on according to requirements. A summary of the author's experience was: Total cases treated, 63; cured, 61; disappeared, 1; abscess of liver, 1; died, none.

Neuroses of the Stomach and Intestines.

Dr. Frank P. Norbury, Jacksonville, Ill., read this paper and emphasized that the background of all was the neuropathic constitution. By using the methods which best combat this feature, and which best subserve the observation of the case and the carrying out of the details of treatment, e. g., the rest treatment, and by studying each case with the consideration of all etiologic factors, the results will be found highly satisfactory.

The Principles of the Diagnosis of Medical Malingering.

Dr. John Punton, Kansas City, discussed this subject in a very exhaustive and interesting paper. He narrated the case which he described in the *Kansas City Index-Lancet*, July, of which an abstract appeared in The Journal, Aug. 1, page 338, No. 69.

Infantile Paralysis; Its Nature and Treatment.

Dr. Albert E. Sterne, Indianapolis, said this was essentially an infectious disease, and was regarded by some authors as the purest form of a true nerve tissue process. Unless epidemic, diagnosis was almost impossible before there was evidence of spinal involvement manifested. When the child first became ill, almost all symptoms pointed to an affection of the stomach, usually a couple of days before paralysis set in. If evidences of profound nervous involvement were found, associated with vomiting, it should serve as a diagnostic and prognostic warning. Counter-irritation should be used along the spine, antiphlogistic applications, and the constant use of dry cold to the vertebral column. Perfect rest should be maintained. No specific is known.

Dr. A. C. Wiener, Chicago, in a paper on the same subject, said that, after nine months had elapsed, any therapeutic attempt was futile. Good functional results were obtained by a brace which would put the paretic muscles of the leg at an advantage over the stronger opponents. The permanent restoration of the balance of two opposing muscle groups might be effected in two ways: First, by implantation of the paralyzed tendon into a normal one of similar function. Second, splitting off a part of the belly of a healthy muscle with its tendon and connecting it with the tendon of a useless muscle. The greatest usefulness of tendon grafting would be found in the frequent cases of infantile cerebral paralysis.

Syphilitic Manifestations in the Nose and Pharynx.

Dr. Paul Turner Vaughan, Hot Springs, Ark., spoke of the rarity of a primary sore in either of these localities. The primary sore should be cleansed with some antiseptic wash and dusted with some mild powder. Calomel is the best he has found. Locally caustics do harm in this stage.

The following papers were also read:

"Surgery of the Thyroid, Historical and Experimental, Illustrated with One Hundred Stereopticon Slides," by Dr. B. Merrill Ricketts, Cincinnati; "Dysmenorrhea" (treatment of nasal cocainization), by Dr. Emil Ries, Chicago; "Therapeutic Value of Heat and Cold Applied to the Spinal Cord," by Dr. W. Frank Glenn, Nashville,

Tenn.; "Brain Strain Dyspepsia," by Dr. C. H. Hughes, St. Louis; "Scarlet Fever," by Dr. J. M. Batten, Huntington, Pa.; "Diabetes," by Dr. A. C. Croftan, Chicago; "Leukemia," by Dr. W. B. Burns, Memphis; "Castor Oil in the Treatment of Typhoid Fever," by Dr. C. C. Bass, Columbia, Miss., (adding 47 more to the 32 cases already reported); "Chronic Intestitial Nephritis," by Dr. R. Alexander Bate, Louisville, Ky.; "The Use and Abuse of Fresh Air and Over-Feeding in Tuberculosis," by Dr. W. H. Prioleau, Asheville, N. C.; "Cyclical Albuminuria" (reporting two interesting cases), by Dr. Arthur R. Elliott, Chicago.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Gastric Ulcer.

According to an article in *Amer. Med.*, in cases in which there is free hydrochloric acid present in excess, bismuth must be given in 30-gr. (2.00) doses three times a day at a time when the stomach is as nearly empty as possible or one dose of 2½ drams (10.00) may be given every morning one hour before any food has been taken. Silver nitrate is valuable in mild cases, especially when hyperesthesia of the stomach is present with intolerance of food, and in chronic gastric ulcer when there is hypochlorhydria or achylia. It acts by producing a thin film of coagulated albumin over the inflamed mucous membrane around the sore. If pain is persistent after the treatment has begun, orthoform should be given in 5-gr. doses (.30) once or twice a day, which will give prompt relief. Patients suffering from chronic gastric ulcer should be kept on liquid food until the ulcer heals or when the epigastric tenderness has disappeared.

Welch, as noted by *N. Y. and Phil. Med. Jour.*, states that the treatment consists in: 1, rest in bed; 2, absolute rest for the stomach until improvement occurs; 3, symptomatic medication. The patient's strength must be cared for, and by giving the stomach complete rest healing is promoted and the tendency to vomiting, pain and hemorrhage decreased. So the patient must be nourished by rectal alimentation. The bowel must be flushed out one hour before the nutritive enema is given, with a pint of normal saline solution. When the rectal feeding is first given the food should be started in small doses and not oftener than once in eight hours. Iron, when anemia is present, may be given with the enemata. The following preparations are recommended as easily assimilated by the bowel: Defibrinated blood in amounts of 5 or 6 ounces at a time or somatose one teaspoonful; two eggs added to four ounces of peptonized milk. This method of feeding should be continued for ten days or two weeks. As to the treatment of the symptoms, thirst is controlled by the enemas and in addition small pieces of cracked ice may be given cautiously by the mouth. Pain and vomiting can often be relieved by external applications of the following mixture:

℞. Spts. chloroformi .....ʒi 30
Alcoholis .....ʒiii 90

M. Sig.: Apply locally to the epigastric regions on flannels.

In cases of obstinate vomiting the following is recommended:

℞. Sodii bromidi .....gr. lxxx 5
Ext. cannabis indicæ .....gr. ss 03

M. Ft. pulvis No. i. Sig.: To be dissolved in three or four ounces of water and administered by the bowel.

The hemorrhage which occurs in about one-half of all the cases is controlled by twenty to thirty drop doses of equal parts of turpentine and egg albumin. And for the collapse due to hemorrhage flooding the colon with salt solution and strychnin and digitalis hypodermically will be of use.

For the hemorrhage gelatin may be given internally in tablespoonful doses of a 5 to 10 per cent. solution every 3 or 4 hours or given hypodermically in weaker solutions. Adrenalin is also recommended given 10 to 15 drops of a 1-2,000 solution three or four times a day. Morphin may be resorted to in stubborn cases and even operation if perforation of the stomach wall should occur.

Leube recommends the following to relieve the pain in gastric ulcer:

℞. Codeinæ phos.
Ext. belladon., ää.....gr. v 30
Bismuthi subcarb. 3i 4
Saech. lactis 3i 4

M. Ft. chart. No. xv. Sig.: One powder two or three times daily.

The following combination is recommended by Hare to relieve the pain and to promote healing:

℞. Argenti nitratis .....gr. iv 25
Ext. hyoscyami .....gr. x-xx 65-1.30

M. Ft. pil. No. xx. Sig.: One capsule twenty minutes before each meal.

In the treatment of gastric ulcer the following combination is recommended by *Columbus Med. Jour.:*

℞. Pierotoxin
Morph. hydrochlor., ää.....gr. i 06
Atropinæ sulph. .....gr. 1/5 013
Ergotin .....m. xx 1 30
Aq. laurocerosi 3iii 12

M. Sig.: Four to six drops ten minutes before each meal.

The following is also recommended:

℞. Argenti nitratis .....gr. v 30
Tinct. opii 3iss 6
Aquæ anisi q. s. ad.....ʒiiss 75

M. Sig.: One teaspoonful three times a day before meals.

Calcium Chlorid as a Hemostatic.

Bartignon, in the *Courier of Med.*, advises the employment of calcium chlorid as a hemostatic in hemorrhages from whatever source, in diseases presenting hemorrhagic tendencies, and especially in hemophilia. According to the author it surpasses in efficiency perchlorid of iron, antipyrin, ergotin, and at the same time is better tolerated by the stomach. He prescribes it as follows:

℞. Calcii chloridi (crys.) 3i 4
Syr. opii .....ʒiii 90
Aquæ .....ʒiv 120

M. Sig.: This amount to be taken in twenty-four hours and renewed so long as the hemorrhage continues.

Terpen Hydrate.

The following methods of prescribing terpen hydrate are recommended by *Rev. francaise de Med. et de Chir.:*

℞. Terpen hydratis .....gr. 3/4 05
Terebenthinæ (Venice) q. s.

M. Ft. pil No. i. Sig.: One such pill four or five times daily; or:

℞. Terpen hydratis
Sodii benzoatis, ää .....gr. 3/4 05
Ext. aconiti .....gr. 1/65 001

M. Ft. pil. No. i. Sig.: Four to six such pills daily.

Phosphaturia.

According to an abstract in *Amer. Med.*, phosphaturia is nearly always associated with some dyspeptic disturbance. The treatment of this condition is rest and the regulation of the diet. Beef bouillon, eggs, brains, sweetbreads, fish, oysters, peas, lentils, turnips, celery and beans. The nitrogenous foods are generally diminished while the green vegetables and fruits are increased. In phosphaturia due to gout, the patient may be instructed to take a teaspoonful of the following for fifteen days three times a year:

℞. Sodii et pot. tartratis .....ʒiii 90
Sodii bicarb. 3v 20

M. Sig.: One teaspoonful in water daily on an empty stomach.

In phosphaturia resulting from overwork, lecithin alternated with arsenic is advised. Lecithin may be given in three-grain doses three times a day for ten days, followed by the following combination, which should be taken for twenty days:

℞. Sodii arsenatis .....gr. i 06
Aq. destil. .....ʒx 300

M. Sig.: One dessertspoonful before breakfast and dinner.

Cod-liver oil is recommended, giving one or two teaspoonfuls three times a day. A combination of calcium glycerophosphate

and the glycerophosphate of iron may be substituted for the lecithin in anemic individuals.

Rheumatism.

L. G. Doane, in *Med. Bul.*, recommends the following combinations in the treatment of chronic rheumatism:

℞. Acidi salicylici 3iii 12
Ext. pruni virg. flu. 3ii 8
Ext. gentianæ flu. 3i 4
Elix. simplicis .....℥v 150
M. Sig.: One teaspoonful every three hours; or:
℞. Ext. taraxaci flu. 3iii 12
Ext. pruni virg. flu. 3ii 8
Ext. glycyrrhizæ flu. .....gtt. ivss 25
Elix. simplicis .....℥v 150
M. Sig.: One teaspoonful every three hours.

Syrup of the Iodid of Iron.

The value of the iodid of iron as a remedy and its range of usefulness is recalled by M. D. Hodge in *Cin. Lancet-Clinic*. The preparation should, as a rule, be given alone and well diluted after meals. The dose may range from five to sixty drops, as desired. He especially calls attention to its value:

1. In the early stages of phthisis, given in one-dram doses three times daily. It promotes secretion, acts as a diuretic slightly, and the weight of the patient increases.

2. In dry, rasping coughs of bronchitis it will soon relieve the congestion and increase the expectoration after the ordinary cough syrups have failed.

3. In amenorrhea and dysmenorrhea, in scrofulous women especially, it is of special benefit, the menstrual flow often being properly regulated. The dose in such cases should range from twenty to thirty drops after each meal.

4. In anemic individuals suffering from chronic rheumatic gout it is of service given in doses of one dram, combined with cod-liver oil.

5. In constitutional syphilis it is a valuable remedy.

6. In children with a strumous diathesis, enlarged cervical glands associated with catarrhal conditions of the throat, and enlarged tonsils, it should be given, administered in ten-drop doses three times a day. It produces marked alterative effect, hastening absorption and reducing the swollen glands and at the same time increasing the hemoglobin.

7. In cases of delayed resolution following croupous pneumonia it is a splendid reconstructive and tonic.

8. In the incontinence of urine in children it serves a good purpose given in twenty or thirty drop doses in water after meals.

Shoemaker recommends the following combination in the treatment of chronic bronchitis and pleurisy:

℞. Pot. iodidi 3iv 15
Syr. ferri iodidi
Glycerini, āā .....℥iss 45
M. Sig.: One teaspoonful in water or milk after each meal.

Medicolegal.

SOME LEGISLATION OF THE YEAR 1903.

California—Requires License for Vending Drugs, Etc.—Chapter CCXXXIII of the Statutes of California of 1903 provides that no person, as principal or agent, shall conduct as an itinerant vendor the business of selling drugs, nostrums, ointments or any appliances for the treatment of disease, deformities or injuries, without a license. An annual fee of $200 is charged.

Arkansas—Provision for County Boards of Health.—Act 42 of the Acts of Arkansas of 1903 provides that the several county judges may appoint county boards of health for their respective counties to be composed of three physicians authorized to practice medicine in the state. A majority of the board shall be sufficient to make any order or perform any duty provided for in this act. The board is authorized to order the seclusion or the isolation of any persons, and any person who shall fail or refuse to obey the order, and who shall be found exposing himself in such a way as to transmit any contagious or epidemic or dangerous disease, shall, on conviction, be fined from $10 to $100, and may be imprisoned in the county jail not exceeding ten days.

California—To Regulate Practice of Optometry.—Chapter CCXXXIV of the Statutes of California of 1903 makes it unlawful to practice optometry without having obtained a certificate of registration from the board of examiners which the statute creates and having filed such certificate with the county clerk. The practice of optometry is defined as the employment of subjective and objective mechanical means to determine the accommodative and refractive states of the eye and the scope of its functions in general. An examination is required before the board, to be confined to such knowledge as is essential to the practice of optometry. Each succeeding year the certificate may be renewed for a fee of $2. The board may revoke any such certificate for conviction of crime, habitual drunkenness for six months immediately before a charge to be made, gross incompetency, or contagious or infectious disease. The act specifies that it does not apply to physicians, etc., authorized to practice in California, nor to persons who sell spectacles in the ordinary course of trade, and who do not employ mechanical means to determine the states of the eye as defined above.

California—Relative to Maternity Hospitals, Etc.—Chapter CCXXXIX of the Statutes of California of 1903 provides that any person who, without first having obtained a license in writing from the county health officers, conducts any maternity hospital, or who conducts any institution or other place for the reception or care of children, or who keeps at any such place any child under the age of 12 not his relative, apprentice or ward, without legal commitment; or who violates the provisions of this act, is guilty of a misdemeanor. Every such license must specify the name and residence of the person so undertaking the care of such females or children and the location of the institution and the number of females or children allowed to be received. Licenses shall be revocable for any violation of the provisions of the act, or in any case where, in the opinion of the licensing body, such place is being conducted without proper regard for the health, comfort or morality of the inmates thereof, or without due regard for proper sanitation or hygiene. Every person so licensed must keep a register of the names and addresses of all such females, the names and ages of all such children and of all children born on the premises, and the names and residences of their parents, so far as known, and the time of the reception and discharge of such children and the reasons therefor, and also the name and age of every child who is adopted or taken away, together with the name and residence of the person taking away the child; and within forty-eight hours shall cause a correct copy of the register relating to a child who is taken out to be sent to the county board of health or county health officer, as the case may be. It shall be lawful for all health officers, at all reasonable times, to enter and inspect the premises, to inspect the license and the register and to see and visit the inmates.

Arkansas—Against Unprofessional and Immoral Conduct.—Act 178 of the Acts of Arkansas of 1903 provides (Section 1) that any physician, surgeon or person practicing medicine who shall employ any solicitor, or drummer, or shall subsidize or employ any hotel or boarding-house, or advertise his business or remedies by untruthful or improbable statements, circulars or cards, or who shall obtain any compensation by any assurance that a manifestly incurable disease is curable, or who shall wilfully expose any professional secret learned from his patient, to the detriment of the patient, or who shall become a habitual drunkard and continue the practice of medicine, etc., or who shall administer any medicine or perform any operation while drunk, shall, on conviction, be punished by a fine of from $25 to $200, and by a revocation of his license. Section 2 provides that whenever any practitioner shall be convicted of any misdemeanor, involving moral turpitude, in addition to any other penalty shall be added a revocation of his license. Section 3 provides that if any practitioner shall commit the crime of abortion, or aid therein (provided

this section shall not apply to any abortion produced by any regular practicing physician to save the mother's life) he shall be adjudged guilty of a felony and punished by imprisonment in the penitentiary for from one to five years, and his license shall be revoked. Section 4 provides that any practitioner whose license is thus revoked may appeal, but shall not practice pending the appeal, and that if he does so practice, or attempt or offer to do so, he shall be punished in the same manner and to the same extent as if he had never had any license to practice. Section 5 provides that after one year from the date of the revocation of his license for these causes a practitioner may ask for and receive a new license, if he shall satisfy the board that he is qualified, has reformed and is worthy.

8 The Treatment of Delirium Tremens. (To be continued.) J. R. Clemens and others.

1. **Hemorrhoids.**—Downes describes his electrothermic angiotribe and points out its advantages over Skene's instrument. He describes the technic of removal of hemorrhoids by this method, dilating the sphincter, using his self-acting anal speculum to expose the areas, seizing the pile area by a suitable narrow-bladed forceps so as not to encroach on the area to be included within the grasp of the angiotribe, then introducing the latter well oiled to crush the pile as near to its base as possible. The shield is then carefully applied and the proper current connected by attaching the cable to the poles near the proximal end of the healing blade. In twenty seconds, he says, it will be noticed that the tissues in the grasp of the blades are cooking, and this amount of current is allowed to act for about ten seconds longer, when the cable is disconnected. A few seconds later a knife should trim the projecting portion of pile from above the blades of the angiotribe, which should be loosened and removed, exposing a white, thin, sterile ribbon in the hollow of the shield. On removal of the shield the ribbon shrinks to the side of the bowel. The same procedure should be carried out on the various pile areas and at the completion of operation a number of bloodless sterile amputation tracks projecting into the bowel and parallel with its axis will be left. A little care is required so that the clamp may not take in the skin margin, though a little of this involved seems to obliterate the nerve filaments. There is never so much pain in this operation, he says, as in others. Unnecessary manipulation during efforts to clamp successfully the pile areas might open one or more ribbons already made, but this is far less likely to occur than with the clamp and cautery, and with proper technic should never happen. The postoperative period in all his cases thus operated on, 25 in number, was much less painful and cleaner than by the various other methods by which he has operated. He thinks it better to put a little gauze into the bowel. In case of fissures he uses his cautery knife and burns through the base of the fissure thoroughly after the completion of the hemorrhoidal operation. In one case he dissected a fissure and closed with catgut. He thinks this method will be very convenient for surgeons provided there is an electric current in the room, but its great practicability is hardly yet understood. He has lately developed a foot brake to turn on or off the current as desired, which places the operator in absolute control. The counting of seconds to get the proper amount of heat in the compressed tissue is necessary, but this is soon learned practically.

2. **Xanthoma or "Mushroom Growth."**—In the case reported by Moser the patient, a boy, was covered with bright yellow tumors of various sizes, chiefly over tendons and bursæ, varying in size from that of a pea to that of a hen's egg. The bases had usually a normal skin structure, were somewhat pinkish in color, had no inflamed areolæ and the tumors were not painful but annoying. He is inclined to consider the growth as a distinct type that may possibly become sarcomatous. Its chief distinctive features are reviewed as follows:

1. The large size of the tumors.
2. Their "mushroom" appearance.
3. Their smooth, even surface, being one mass, and not nodulated, tuberculated and fissured, as in the ordinary form of xanthoma tuberosum, which is formed by the coalescence of smaller masses or papules and is not infrequently associated with the macular variety of flat plaques or striæ, which in this case were conspicuously absent.
4. Their predilection for tendons and bursæ.
5. The absence of icterus.
6. The absence of glycosuria.
7. Their occurrence in childhood, which is very exceptional for xanthoma tuberosum, most cases occurring in middle life, especially in women.
8. Their subcutaneous character.

3. **Uterine Curettement.**—Van de Warker strongly objects to the too frequent use of curettement, especially the use of the sharp curette, pointing out the serious dangers of bowel perforation, etc. He says the text-books and surgical teachings are at fault in this matter. He gives instances of the bad effects and describes the proper aseptic measures required and the technic, character and treatment of complications, such as uterine perforations. In this latter case it would be necessary to see that there has been no hernia of the bowel or omentum through the wound. This will require a free opening. He thinks it is better in this case to incise the cervix clear up to the inner neck to allow the finger to pass freely, and if hernia has occurred it should be reduced. The probability is that it will not come down again, but if the rupture is extensive, gently applied strips of gauze pressed against the uterine side will prevent hernia. They should not be inserted into the wound, which would interfere with healing and contraction. Then the peritoneal cavity should be opened through the postvaginal space and wiped out with a sponge on a long curved holder, and gauze inserted to the level of the fundus and brought into the vagina. If the intestine is torn and it is necessary to open the abdomen, in case the uterine tissue is friable, no attempt should be made to suture the uterine wall, but slide a flap of peritoneum over the rent and suture with fine silk. The uterine rent can be left to itself. An abdominal incision adds enormously to the dangers in these cases and should never be done except to repair intestinal damage.

4. **Epididymis Anastomosis.**—Martin reports a case of sterility due to earlier urethritis and double obliterative epididymis in which repeated examination failed to show the presence of spermatozoöids. Operation was performed and spermatozoöids found in the tail of the epididymis. The vas deferens was implanted into the wound and sutured with a fine silver wire and the skin closed with catgut. The dressing slipped the next day, exposing the wound, which became infected and suppurated superficially. Later examination showed normal seminal fluid. The patient completely recovered, and his wife, on resuming sexual relations, was delivered of a normal girl baby exhibiting a striking resemblance to her father.

17 *Notes on Obstetric Therapeutics. Charles M. Green.
18 *Recent Advances in the Therapeutics of Pediatrics. Noble P. Barnes.

10. The Teaching of Therapeutics.—Long advocates the case method, or what may be called the Socratic method, where students and teachers meet for discussion of cases and their treatment. The discussion is given direction by the teacher, but each student is free to ask questions and state opinions. The marking is based on ability to develop or reason out points in the discussion. Various diseases are gone over and the student is expected to acquire a knowledge of the principles of treatment, the ability to weigh indications and contraindications and reason out a rational plan for each case, as also to learn the relative importance of hygiene and medicinal treatment and the various drugs to be employed. It gives him a more intimate knowledge of the remedies of greatest importance and those of subordinate or uncertain value, and a valuable medical training that he will need in actual practice.

15. Electrotherapeutics.—Morton reviews the advances in phototherapeutics, summing up by saying that all the artificial sources of light possess only a feeble power of penetrating living animal tissue until prior compression (as by Finsen in lupus) is employed. There is really but one conclusion to be drawn, and that is that all forms of solar, electric arc and other artificial lights are entirely supplanted in their efficacy and usefulness by the *x*-rays. These may in turn give way to Becquerel's radiations, but the present cost of radium is prohibitive. Recent advance in phototherapy, therefore, consists in an increasing clinical experience with the *x*-rays. In the selection of a working tube, a soft tube will do superficial work while the hard tube is better for deep structures and is safer. The question whether an *x*-ray burn can be a cancer nidus is answered in the affirmative and 4 instances noted. Morton also mentions the possibility of secondary infection of open cancer. The use of the Crooke's tube itself gives evidence of this in its attraction for dust, and what is true of the tube is equally true of the patient. The case is as if we sprayed the dust of the room directly into the ulcer. In conclusion he calls attention to the *x*-ray histofluorescence with which he has practiced for some time, and this may be considered as possibly an advance step in the treatment of cancer. It occurred to him he might administer a drug medicinally, capable of fluorescence, and at the same time increase its fluorescence in the tissues themselves by means of the *x*-ray. He can not affirm it, but he believes that cases treated by a combination of fluoresceing medicines and the *x*-rays have made more improvement and more certain recoveries than cases not thus treated.

17. Obstetric Therapeutics.—Green discusses the use of antistreptococcic serum and the intravenous use of formalin for puerperal sepsis. He has observed 3 cases of ineffective formalin injections, "2 died in spite of, and 1 recovered notwithstanding, the use of formalin." A safe and effective intravascular antiseptic agent against the streptococcus is not known. He notices also obstetric asepsis and the use of suprarenal extract as an astringent and hemostatic in uterine hemorrhage. He goes at length into the subject of obstetric anesthesia, giving his own experiences with the scopolamin-morphin admixture recommended by Von Steinbüchel as an ideal anesthetic for obstetric use. Scopolamin hydrobromate and morphia nitrate were so combined that ten minims of the mixture contained 1/200 gr. of the former and 1/6 gr. of the latter drug; administered hypodermically. Some 16 cases of primiparæ thus treated are reported with good results. In 3 multiparæ it seemed to have less effect in relieving the pains. He remarks that as a result of these observations it would seem that in the scopolamin-morphin narcosis we have a valuable addition to our obstetric therapeutics. The combined drugs seem especially serviceable in primiparæ of nervous, excitable, hyperesthetic organization. The best results are obtained when the drugs are given early in the first stage as soon as nervous irritability appears. He remarks in regard to puerperal eclampsia that recent experience has taught him that in hyoscin and morphin in heroic doses we have a potent agent for the control of extreme restlessness and maniacal excitement. Three cases are reported. As regards the prophylaxis of the condition he says he has never had a case of puerperal eclampsia among women who have been under his care during pregnancy. All the cases he has seen have occurred in consultation or hospital practice. Careful attention to diet, hygiene, the condition of the nervous system and the functional capacity of the eliminative organs has brought him suitable results in cases where he has supervised the condition from the beginning. Nicholson's theory that the use of thyroid extract is indicated in eclampsia, the latter being due to thyroid inadequacy, Green considers worthy of further investigation.

18. Pediatrics.—Several points of interest are mentioned by Barnes: The importance of adapting children's clothing so as not to interfere with muscular development; the usefulness of thyroid in mammary inactivity; the danger from tuberculous milk; the treatment of anemia; the isolation of contagious diseases in children; the use of antistreptococcic serum in scarlet fever; the usefulness of guaiacol and creosote carbonate in pneumonia, and the valuable therapeutic advantages of lumbar puncture, as well as its diagnostic utility.

23 Congenital Absence of Rectum with Imperforate Anus. G. W. Squires.

19. Fibrocystic Tumors.—Jones discusses the literature on the etiology of fibrocystic tumors, pointing out that the majority of cases that have been described are fibrocysts of tumors, and reports cases of fibrocysts of the uterine tissue itself. There is a change of the whole uterine tissue and the formation of partial blood cysts. She gives her ideas as to the formation of blood corpuscles and inflammatory bodies and claims that all abnormal growths are in a pathologic condition and in a state of change, and possibly in these cases are developing into even more serious conditions, such as malignancy, etc.

20. Copper in Syphilis.—Price notices the intolerance of copper in old syphilis, and the results of his treatment with small increasing doses. An experience of many years, he says, has led him to formulate his belief as follows:

1. The treatment of syphilis in all its stages, inclusive of the cachectic and the parasyphilitic forms, is well founded on sulphate of copper in the average dose of 1/30 gr., aided by such a quantity of blue mass as is borne readily by the patient.
2. In old syphilis in any form the copper salt must be given in minute doses, and gradually increased as tolerance is established, until the usual dose of 1/30 gr. is given, when the mercurial should be added in a rather small dose. It is sometimes better to give the medicine only on alternate days.
3. In acute syphilis the copper salt is to be given in the dose of 1/30 gr. and the mercurial added at once and increased as much as the patient will tolerate, in order that the disease shall be neutralized and eliminated as completely as possible.
4. Iodin, iron, arsenic and tonics of any sort, while useful, occupy a subordinate place in the treatment of syphilis.
5. Alcohol and, especially, tobacco, should be forbidden to syphilitics.

25 *The Operative Treatment of Umbilical Hernia. J. Collins Warren.
26 *Vesico-intestinal Fistula. Joshua C. Hubbard.

25. Umbilical Hernia.—Umbilical hernia in children rarely comes under the surgeon's care, as it is usually kept reduced by a suitable support until the opening disappears and a cure is effected. The typical surgical case is that of a woman of middle or advanced life, corpulent habit and mother of a large family. The etiology seems apparently to be the changes of pregnancy and the relaxed condition in which the parts are left, the force of gravity and the pressure of clothing causing giving way of the weakened walls. As the adipose tissue accumulates, the cicatricial tissue of the umbilicus is drawn on

and drags the funnel-shaped fold of peritoneum through the true abdominal wall. While this form of hernia has generally been considered more liable to relapse than the others, recurrences, Warren says, are becoming fewer with improved conditions. This is not due to new methods but to more care in suturing and in perfecting the operation. The hernial sac should be exposed by two slightly curved incisions on the median line, meeting above and below and exposing the walls of the sac as far as the neck and surrounding aponeurosis. It should then be opened and the contents freed from adhesions and returned into the abdomen. If the omentum is matted together it had better be excised at a point below the portion usually occupying the sac. The sac should then be carefully excised and the vessels secured. The opening that is left in the abdominal wall is oval, with its long diameter lying at right angles to the linea alba. The peritoneum should, if possible, be separated from the fascia and secured by fine sutures. The edges of the hernial ring consist of the tendinous raphe formed from blending of the aponeuroses of the abdominal muscles. The accurate coaptation of these edges is important and is best effected by closing the ring transversely instead of vertically, which is much easier. The material used for suturing the peritoneum is fine silk, No. 8, such as is used for intestinal suturing; No. 10 silk is used for suturing the aponeurosis. Enough of this layer should be taken up to hold the sutures securely. Warren does not advise the use of quilted or complicated sutures or exposing the edges of the recti except in rare cases of wide separation. In aseptic wounds attention to the above-mentioned points is enough. The adipose layer and outer integuments should be trimmed with a knife so as to fall easily into apposition. This involves excision of the umbilicus and a certain amount of skin on either side. The adipose layer is then caught together by medium silk sutures and the skin united by silkworm gut. A new feature in the treatment of these cases is excision of the thick layer of adipose tissue, sometimes several inches in thickness in the median line. To remove this a median incision should be extended through the skin and subcutaneous adipose tissue from a point two inches below the ensiform cartilage to the transverse fold defining the upper limit of the mons veneris. The skin, with the adipose tissue still attached, is then dissected away until the integument has been freed as far as the loins. The vessels that are divided are easily secured. After hemorrhage has been arrested the skin should be attached to the aponeurosis by two or three catgut sutures to prevent dead spaces, and the edges of the skin should be united in the usual way by silkworm gut. This leaves a long cicatrix, but it contracts considerably with time. It is a better method than the transverse or crescentic-shaped incision by which the fold itself might be excised. He reports a number of cases from his practice.

26. Vesico-intestinal Fistula.—After reporting a case in detail in which the patient died in a postoperative delirium, Hubbard describes the condition, which is most frequent in males, three cases to one in women. This is partly due to the intraposition of the vagina between the bladder and rectum. The cause seems to be an inflamed perineum or inflamed new growth of the uterus and its adnexa, the primary focus invading secondarily the bladder and intestines thus forming a fistulous connection between them. The fistula is usually rectal, next to that in frequency the sigmoid and colon are involved, and occasionally the ileum. The symptoms are discharge of gas and fetid matter through the urethra and urine through the rectum. There are usually pain and vesical and rectal tenesmus, cystitis, pyelitis, etc., caused by the presence of the fecal matter, but sometimes the discharge of gas alone is the only symptom. He points out the various conditions which may need to be differentiated from it, such as the condition of the bladder after catheterization or litholapaxy or diabetes, which may develop the gas, and the possibility of the existence of fistula, with an intestinal opening into the urethra below the bladder. The prognosis depends primarily on the cause of the fistula and, in simple inflammatory fistula, largely on its size. Palliative treatment is devoted to keeping the bladder and rectum clean by thorough irrigation and drainage or in some cases by the position of the patient. He mentions the various methods of cutting for fistula, the rectal route, the perineal route, the sacral route, the vesical route, which is difficult, and the abdominal route. The best results appear to be with the rectal or perineal routes. The causes of death in the fatal cases have been peritonitis and shock.

32 *Some Observations on Trachoma. A. A. Ripperger.
33 Eye Strain and Civilization. George M. Gould.

28. Tuberculosis.—Rochester would have two types of sanatoriums, one for the incipient cases and another for the chronic ones, but the essential point is removal of the patient from his surroundings. He remarks in favor of this, claiming that the procedure is not unprecedented and the good to the entire race from such sequestration kept up persistently for ten or fifteen years would far outweigh the slight psychic disturbance of the few. The bodies of all dead from tuberculosis should, of course, be cremated.

32. Trachoma.—Ripperger gives the results of his own experience, which seems to show that uncleanliness and close huddling together of people under unhygienic conditions favor the spread of the disease. He also remarks on the advantages of protargol in treatment.

43 *Fibromata as Complications of Pregnancy. Reuben Peterson.

41. Whooping Cough.—Sobel calls attention to Naegeli's method of relieving paroxysms of whooping cough by pulling the lower jaw downward and forward, a procedure which has not been noticed to any extent by recent writers. He has used this method in all cases of whooping cough presenting themselves at the dispensary for children's diseases at the Beth Israel Hospital, New York, since June, 1901; a total of 96 cases, the age ranging from three months to eight years. No selection of cases was made and all stages were observed. He has had only 9 failures out of the 96 in which no effect on the paroxysm was produced by this method. He claims that the method is usually more successful in older children. In cases without the whoop the expiratory spasm with its asphyxia is generally overcome. The method deserves a place in the treatment of pertussis and is as successful as any other. It is harmless, painless, and easy of application. The only contraindication to it is the presence of food in the esophagus or mouth. A patient treated this way is less likely to suffer from complications and sequelæ than those treated only medicinally. Mothers and attendants should be instructed in the method. The best other treatment should accompany.

47. Nasal and Salivary Secretions in Hay Fever.—Kyle thinks from a study of the saliva we can gain some idea as to variations in the chemistry of the body. He applies this suggestion to the etiology of hay fever, holding that there has not yet been determined a definite cause. He thinks in many cases local irritation of the mucous membrane is brought about by some chemical change in the secretion of the mucus-secreting glands, and that there is quite a field for investigation in this line to determine if the irritating material bringing about an attack is not manufactured within the system.

56 A Glance at the History of Medicine. Charles D. Center.

51. Atony of the Stomach.—Salisbury agrees with Stiller as to the importance of the splashing sound and the floating tenth rib as signs of the condition. He concludes that mobility of the tenth rib marks an arrest of development connected in some way with imperfections in the abdominal organs manifesting itself particularly in atony of the stomach and intestines and corresponding atony of the ligamentous tissues and skeletal muscles, especially of the abdomen. The only common structure that we can suppose to produce this symptom is the nervous system, hence he refers all manifestations that follow this to disturbance of the nervous system affecting the nervous supply of the abdominal organs and corresponding external parts. The consequences of atony are, first, the imperfect mixture of the ingested food with the gastric secretions. Gaseous fermentation rarely occurs unless the food is retained too long, though other fermentations may develop, producing trouble. Other symptoms which are likely to occur are the entrance of bile from the duodenum through the relaxed pylorus and the prolongation of the digestive act beyond the time when the stomach should be empty. Often a second meal is introduced into the stomach that has not relieved itself of the first. The question of atony terminating in dilatation is discussed. He thinks that probably every degree results in a temporary and slight degree of dilatation. Retardation of digestion has a tendency to set up gastritis. The prognosis of chronic atony ofthe stomach depends more on the complications than the disease itself, and the tendency to gastroptosis is a marked feature. The discovery of a floating tenth rib may enable the physician in acute debilitating diseases to put the patient and friends on their guard and save trouble, especially if the disease is of a disabling nature. The disorder must be recognized as an affection of the nervous system demanding general systematic tonic treatment. Rest in bed is an important adjunct; care as to the diet, a nutritious and not too bulky one, and repeated analyses of the stomach contents to test the digestive capacity, are of importance. Cold bathing, massage, electricity, etc., exercises to strengthen the muscles of the trunk, play important parts in the treatment. The faradic current is to be preferred to the galvanic.

52. Tuberculosis.—Pottenger considers that tuberculosis is the most frequent of fatal diseases and gives tables showing the mortality in different countries. While we have been obliged to discard heredity as a common cause, he thinks we have gone too much to the other extreme and neglected the question of predisposition. Childhood is a period that needs our most earnest attention, and while we must recognize the possibilities of heredity, most of the trouble comes from environment. Our hope as to the future prophylaxis of tuberculosis largely depends on our attention to this point. Overcrowding is one of the most active causes in rendering the environment unhealthy, and the part played by acute infectious disease, especially in childhood, deserves earnest consideration. He also cautions against over-exercise and over-training as a possible cause.

54. The Eye Complications of Measles.—Suker reviews the various eye complications as they occur in measles, the most frequent of which are conjunctivitis and superficial inflammatory conditions. Fundus complications are rather infrequent as well as other deep-seated disorders. The possible complications are reviewed in detail. Among the more frequent ones are mentioned catarrhal and follicular and phlyctenular conjunctivitis and phlyctenular keratitis. In both phlyctenular complications the gastro-intestinal tract must be looked after as the possible source of an auto-intoxication. Marginal blepharitis is a common accompaniment of measles. Photophobia and asthenopia are also common. Of the deep complications optic neuritis and neuroretinitis are the most frequent of the fundus conditions. Total blindness coming on during an attack is rare. Muscular insufficiencies are sometimes noticed. In some cases strabismus has been credited to the disease. Disturbances of accommodation of the peripheral type are sometimes observed after apparent recovery in measles as in diphtheria. Non-inflammatory complications scarcely require treatment except rest for the eyes and tonics. The strabismus should be treated as if from any other cause and inflammatory disorders receive such treatment as would ordinarily be suitable. Suker thinks, however, that it would not be amiss to employ mild prophylactic treatment in the scrofulous or greatly debilitated cases so as to guard against phlyctenular complications and continue this for several weeks.

57. Hypertrophic Osteo-arthropathy.—Two cases are reported by Janeway illustrating the symptomatology of the Marie and von Bamberger types of this condition. He discusses the theories and reviews cases he has found in the literature with regard to the etiology and pathology of the affection, and concludes that the incidence of osteo-arthropathy and tubercular pulmonary lesions is too marked to be made light of. Other associations are suppurative, gangrenous, etc., but some cases seem to have occurred without being apparently secondary to any known disease. He remarks that great individual differences in the reaction of the bones to irritants evidently exist in different persons. He asks for a careful recording of cases of osteo-arthropathy and allied conditions by the radiograph, as the problem of its true etiology requires a larger knowledge of bone pathology and of pathologic metabolism than we now possess.

60.—See abstract in THE JOURNAL, xl, p. 1669.

62. Congenital Hip Dislocation.—Four cases are reported by Davis involving seven hips. One was operated on and one was

lost sight of while under treatment. Of the other 5, 2 were anterior transpositions; 3 were apparently perfectly normal in every way, five, two and one-half years and six months after replacement by manipulation. He reviews the methods of open and forcible bloodless reposition and notes their respective advantages. The general conclusion is that perfect reposition is rarely attained in forcible reposition. As an absolute cure it hardly meets the full claims. If one is critical as to cures like Kirmisson, Hoffa, Kollicker, Schede, Codivilla and others, we can call 5 per cent. cured, but if one is more easily satisfied then the cures will amount to 50 per cent. It is probable that total failure under the age of 6 to 8 years is rare; that approximately one-half the cases are replaced in a more or less normal acetabulum and kept there; that a small proportion are apparently quite normal; that in most of the remainder the head is transposed forward or forward and upward and remains there. In many of these cases subsequent operation may perfect or improve the condition. Others seem to do well and still others have a tendency to slip backward to their former condition. It is absurd to speak of a cure within a short time after reposition. One should be cautious as to promising results of treatment.

69.—See editorial in THE JOURNAL of October 10, p. 913.

70. **Bovine Tuberculosis.**—From a careful study Kober concludes that tuberculosis may be transmitted to man in milk from tuberculous cows. The danger is real and can not be measured by the actual number of recorded cases, but should be judged, in part at least, by inoculation and feeding experiments and the accidental wound infection that has occurred. The degree of danger may also be estimated by the prevalence of bovine tuberculosis and of the forms other than phthisis pulmonalis in man, remembering that the infectious qualities are greater when the udder is the seat of lesions, and that Gebhardt's experiments show that tuberculous milk when diluted with milk of sound animals in the proportion of 1 to 40 loses its infective power. Experiments also indicate that while the bacilli of human tuberculosis possess different degrees of pathogenic power and are often of feeble virulence for cattle, Koch's claim that human and bovine tuberculosis are distinct, and that human tuberculosis can not be conveyed to cattle, appears to be disproved aand his failure to secure results may be attributed to the use of human bacilli of diminished virulence. Recent studies have strengthened Smith's claim that there are two types of tubercle bacilli, the human and bovine, with morphologic and biologic differences, but both of these may produce virulent cultures which, when inoculated into animals, produce the disease. It is desirable to have further study as to the frequency of primary intestinal and abdominal tuberculosis in all cases, whether the child died of tuberculosis or not, and bacteriologic examination should be directed to the existence of both of these types. As to whether the bovine type predominates, a careful chemical analysis of the milk of tuberculous animals should be made to determine the amount of phosphoric acid as compared with the quantity in normal milk, since de Schweinitz's researches seem to show that the excess noted by the older chemists is really the result of bacterial activity in the udder of the cow. The pathologist need not reverse his opinion as to the identity of human and bovine tuberculosis and the sanitarian has no reason to assume that the human subject is immune against infection or to cause him to relax his efforts in preventive measures.

71. **Tabes in the Negro.**—Hecht reports a carefully examined case and discusses the disease, especially in its occurrence in the black race. He concludes that long residence with the white man has made the American negro anthropologically, physiologically, and pathologically different from the original stock. This has been due to acclimatization, social environment and more than anything else to miscegenation. This latter and the advent of personal liberty are responsible for a new era of diseases. The newer diseases in the negro, of which tabes is an example, are becoming more commonly recognized, miscegenation being the potent factor in reducing the negro's resistance. Tabes probably occurs more commonly than has been supposed, and the failure to recognize it may be due to the abeyance or total absence of the ataxic symptoms in the amaurotic type. The Edinger-Marie observations as to optic atrophy satisfactorily explain that class of cases in which the tabes is arrested by blindness. Finally he concludes that Aryan admixture is essential to the production of tabes in the negro.

75 The Hypothesis of Cohnheim Concerning Carcinoma. Algernon T. Bristow.

72. **Urinary Casts.**—The clinical significance of hyaline casts is open to many qualifications, according to Emery. They may be dependent on weakened or disturbed circulation or subject to altered conditions of the blood and febrile conditions. If the casts are small or medium sized and not accompanied by albumin and not numerous, or occurring in a man over 45 years old, they need not be considered necessarily of special significance, but if they are large or medium sized in large numbers, further examination and careful inquiry are indicated. The appearance of hyalin casts containing granular matter does not always indicate an active destructive process within the kidney, nor do small hyaline casts in young persons after exhausting or long-continued severe exercise. Large hyaline casts in the urine of middle-aged persons, if long continued, may indicate beginning intestinal nephritis. If there is a continued trace of albumin, suspicion should be excited to the point of certainty, especially if the daily output of urea is decreased. The occurrence of epithelial, blood or granular casts in the urine is of sufficient gravity to call for systematically conducted chemical and microscopic examination, though such may occur from localized infarcts which heal up. In patients ill from tonsillitis, pneumonia, and typhoid, albumin and casts may appear and no detrimental effects follow. Bacterial casts are occasionally seen and are of importance. Waxy casts are often of grave import. He suggests in cases in which it is impossible to obtain a twenty-four-hour specimen which can be identified as such to make a series of examinations at intervals during several weeks.

76. **Tuberculosis of the Genital Organs and Peritoneum.**—Veit finds that this is more frequent than was formerly supposed, and while it may be primary, the secondary form is the most common. It is usually descending, more rarely ascending, but the infection may also follow the blood vessels or occur after accidental injury of the lymph glands. The diagnosis is based in particular on the discovery of the bacillus; in some cases, however, the certain occurrence of tubercles is sufficient. Recovery may be spontaneous. In primary isolated genital tuberculosis operative treatment, however, is still the best. In secondary tuberculosis or cases not isolated, the general therapeutics must be first considered, especially constitutional treatment. Good and permanent results are sometimes obtained from operation and, exceptionally, this may be considered. The best local palliative is iodoform. He says that tuberculosis of the peritoneum is always secondary. There are two forms, the ascitic and the adhesive. It may be secondary or primary. Peritonitis, with extensive nodule formation, which can not be explained by ovarian tumors or carcinoma, must generally be considered as tubercular. It may even heal spontaneously, though not very frequently, and is cured by laparotomy, even though some failures, due mostly to too far advanced tuberculosis in other organs, do occur. A generally accepted explanation of this healing process does not exist;

the influence of the serum (whether normal or antitoxin) is very probable. Therapeutically speaking, therefore, recent cases should be operated on when difficulties arise as the result of disease. A repetition of the operation may, if it is performed very early, become necessary. Chronic cases should be observed, and if spontaneous recovery does not soon occur, laparotomy should be performed. A simple laparotomy along the linea alba with evacuation of the fluid and closure of the abdominal cavity is usually sufficient. The abdominal radical operation should be performed only if at the same time we find a completely isolated genital tuberculosis. Veit's article was one of the principal addresses at the last international congress of gynecology.

77.—This article appeared elsewhere. See THE JOURNAL of October 17, ¶7, p. 985.

79. **Instrumental Dilatation of the Cervix.**—Lott redescribes a metallic dilator invented by him, a description of which was published in the *North Carolina Medical Journal* in 1892. Bossi's dilator was first described in an Italian journal in 1891, and Lott's invention was entirely without knowledge of the Italian's work. It was employed successfully in this country ten years before the Bossi invention was here introduced.

80. **The Effects of Anesthetics on the Temperature.**—Morley gives his observations on the effect of anesthetics on temperature. He concludes that ether anesthesia lowers the body temperature; that this is due to the increased heat output through the dilated skin vessels and to lessened heat production from diminished muscular movement. Hence the patient should be well protected with lint and bandages and the operating room should be warm. Many of the so-called postoperative pneumonias are due to the chilling of the patient.

87. **Chronic Nephritis.**—Vaughan reviews the dietetic instructions of various authorities. He criticises the exclusive milk diet. The diet which Vaughan has found most serviceable in chronic nephritis is, with the exception of cream and butter, wholly vegetable. He forbids meat in every form, eggs and milk. What he seeks is to profoundly alter the proteids in the circulating blood, and believes he has the best reasons for the selection of the vegetable diet. The urine for twenty-four hours should be collected and its albumin carefully determined, both absolute and percentage, also the amount of urea and total nitrogen should be ascertained. Then the patient should be placed on a diet for three days or more and corresponding analyses made. The diet permits cream, which should be separated as quickly as possible from the milk, and should not contain more than 1 per cent. of proteid. The amount of cream per day is limited to 500 grams, or one pint. Among the cereals he prefers cornmeal mush, which may be allowed *ad libitum*, or oatmeal and cracked wheat may be substituted. Sugar is allowed freely for the mush and zwieback and butter and potatoes complete the substantials of the ration, although he permits the legumins, peas and beans either fresh or canned, green vegetables, fruits and melons. Patients living on such a diet have no difficulty in becoming accustomed to it and lose their desire for meat and eggs. He tabulates the number of calories in this diet, showing that it is sufficient. In order to scientifically determine the value of such a diet in chronic nephritis it will be necessary to test the relative toxicity of the blood of the patients on animals, especially with reference to its action on the kidneys under different diets. This offers a promising field of research. He considers the diet as important in nephritis as in diabetes. The digestive organs need to be carefully watched. Lavage of the stomach is frequently indicated and an analysis of the gastric juice should be made in all cases. The eliminative organs, bowels, skin, etc., should be kept in normal condition, but not too active. Flannel clothing, varying according to the seasons, should be used. Blood counts and hemoglobin estimates should not be neglected.

88. **Renal Decapsulation and Bright's Disease.**—Coe relates his own case and his observation of others treated by Dr. Edebohls and two cases from his own operative experience. He has become an advocate of the method from these observations. He suggests to those who will try the surgical procedure to keep the patient in bed for one week preceding the operation, examine the mixed twenty-four-hour urine for reaction, quantity, albumin by the Esbach or better still by the centrifuge method with potassium ferricyanid; supplemented by repeated estimation of urea for total average quantity. Some value can be attached to the lessened quantity of chlorids as demonstrating renal insufficiency. He says do not trust the settling glass for examination for casts; use the centrifuge. Do not think there is no nephritis because there is no albumin; use the contact test. Conspicuous edema is not essential. Be sure of the condition of the heart and blood vessels. Do not belittle the difficulties of operation, which may be simple or complicated according to the thickness of the walls, the high position of the kidneys, the shortness of the pedicle, possible injury to the nerves or puncture of the pelvis. He believes in the use of the method in eclampsia; in the hands of a rapid operator he would suggest it as the operation of choice. The danger of anesthesia he says may be negative. He is using at present in all his major operations the Bennett inhaler and combined nitrous oxid and ether anesthesia.

98. **The Encephaloscope.**—The treatment of brain abscess is a difficult subject and very few if any have duplicated the successful results of MacEwen. It is dangerous to introduce

gauze into the abscess, the walls of which are especially delicate. Whiting has devised an encephaloscope, consisting of a hollow metal tube with flaring orifice and slightly contracted extremity, very similar to an enlarged type of ear speculum. Into this tube an obturator fits in such a way as to accurately occlude the extremity and preclude the possibility of laceration of the soft brain substance which must be displaced or thrust aside when the instrument is introduced into the abscess cavity. This obturator can be quickly withdrawn or speedily replaced should circumstances require. He describes the appearances in acute and chronic brain abscess. In the former there is simply a space with pinkish or reddish walls, with here and there thin shreds of plastic lymph, but nowhere any appearance of an investing layer. Chronic abscess, on the other hand, has a marked yellowish white opaque capsule distorted and irregular in shape and dense in structure. When the examiner looks through the encephaloscope, the interior of which is illuminated by a head mirror, he notices that the collapsing walls come in contact with one another, except where there is a slight depression which, of course, corresponds to the situation and direction of the drainage path. If this lies in the center of the field of observation the obturator can be replaced into the tube and the instrument carried one-half an inch deeper into the brain and straight forward. If it does not correspond with the center of the field, but is situated below the center, to the right, left or above, it is inclined in the direction corresponding to the depression and is carried by gradual stages and repeated observation until the bottom of the pus sac is reached. For acute brain abscess he would adopt an entirely different plan from that with chronic abscess. He would simply introduce to the bottom of the cavity a single wick of iodoform gauze the size of a crow quill, the dressing to be changed at intervals of forty-eight hours until the surface exposed to view is seen to be covered by pinkish granulations. Then the length of the drain should be reduced and the depths of the abscess permitted to heal, preliminary to complete closure of the canal from the dura inward. In chronic brain abscess where there is a dense, firmly-resisting, fibrinoplastic membrane which must slough away or undergo absorption, he would mop the cavity clean with sterile cotton and introduce sufficient iodoform gauze to distend or balloon it, which must be kept up until all fetor disappears and the former lymph-coated suppurating surface is covered with small, red granulations. With the appearance of these granulations favorable and speedy healing may be anticipated. He thinks curetting of a chronic brain abscess cavity might be done with great care, and when large tufts of necrotic granulations are seen they might be scraped away so that they will not conceal a path of infection extending into the adjoining brain tissue. His experience with brain abscess comprises 8 cases, 3 treated without the encephaloscope with gauze packing with or without irrigation. There was 1 recovery. With the encephaloscope he has had 5 cases and treated them all with gauze packing without irrigation with 1 death. This change of mortality from 66 per cent. to 20 per cent. is, he thinks, decidedly in favor of the instrument so far as his experience goes.

7. **Maternal Circulation in Pregnancy.**—Certain normal changes occur in the blood during pregnancy; it is increased and more dilute. Nicholson, however, notes certain abnormal conditions. With the hypertrophy of the heart that occurs, especially of the right side, showing itself by pulsation in the jugular vein, there is still likely to be some overstrain; If the normal heart is dilated in pregnancy the arterial pulsation does not always show it, and this form may often be found in a woman who exhibits large pulsations in her jugular. The type of the radial pulse is quite consistent with the left ventricular hypertrophy, and yet other evidence points to dilatation of the right heart. He thinks the explanation is not a simple one. There are possibly toxic influences of some sort at work. The peripheral resistance is often increased and the protective action of the cardiac and vascular reflexes are interfered with. He thinks it is not improbable that some powerful and universal vasoconstrictor is generated during pregnancy; something which produces similar effects to those of suprarenal secretion and at other times the thyroid action seems to be increased. One or the other of thyroid or suprarenal secretions seem at times to gain the upper hand and patients that have a decided increase of blood pressure without edema, or only a firm or solid one, have no tendency to postpartum hemorrhage, but are likely to develop eclampsia and the arterioles must be relaxed. Thyroid extract, he thinks, is the ideal vasodilator for this purpose, and for an emergency a full grain of morphin hypodermically is the proper treatment.

11. **Alcohol.**—Hyslop considers that alcohol always has an evil action in healthy individuals, though it may be used wisely in times of need as a stimulant, nutrient and antipyretic. Stimulating a worn-out machine, however, by improper fuel is not productive of good results. He makes a comparison with financial conditions and claims that alcohol is only useful as a loan to avert physical bankruptcy. It may help to tide over a bodily crisis until the organism can repay the loan with its accumulated interest. The action of alcohol on the nervous element is noted, as also the changes in alcoholic insanity.

12. **Alcohol and Human Evolution.**—Reid reiterates his opinion as to the effect of alcohol in weeding out the unfit and thus acting as a decided factor in human evolution. In the discussion that followed Mercier, Yellowlees, Kelynack, Edridge-Green, Schofield, Ridge, Ford Robertson, Lloyd Andriezen and other prominent alienists and neurologists handled Reid's theory pretty severely.

13. **Blood Serum in Insanity.**—Johnson and Goodall have experimented to ascertain the effect of the action of blood serum in the different forms of insanity on cultures from mixed strains of *B. coli communis* in order to find whether by the determination of agglutinins direct evidence can be adduced of the morbid influence of the colon bacillus in such cases or the indirect evidence of similar action on the heart of other organisms related to the colon bacillus. Twenty-five cases of insanity of various kinds were tested; good agglutination was shown in 4 out of 5 cases of acute melancholia; 1 out of 3 cases of general paralysis; 1 out of 2 cases of delusional insanity, and 1 case of climacteric insanity. Partial agglutination appeared in 6 out of 11 cases of acute mania; 1 out of 2 cases of delusional insanity; 1 case of alcoholic insanity. No agglutination occurred in 5 cases of mania, 1 of melancholia, 1 of puerperal insanity, 2 of general paralysis and 1 case of recurrent mania. Agglutination, therefore, was present in 60 per cent. of all cases; in 28 per cent. good, in 30 per cent. partial. With control experiments, which were made each time, only one showed a slight partial agglutination. The authors have also followed the method of Bruce in counting the number of leucocytes in various cases of insanity at regular intervals over a definite period of time, and they find the leucocytes were in much greater numbers during the acute stages, falling again in remissions and cases of recovery. They were mostly of the polymorphonuclear type. The highest number occurred in acute mania.

14. **Fragilitas Ossium in the Insane.**—Smith has studied the conditions of patients as regards the breaking strain of their ribs in 200 cases from the postmortem records in the Wakefield Asylum. The forms of insanity in which the fragility was most marked were chiefly paresis and dementia; only 1 case of melancholia, and none of mania, under forty-four,

showed this symptom. In epilepsy it seems to be less frequent than in some other forms of mental disorder. The results of the data show that:

1. In percentage cases those of dementia are the highest and those of epilepsy the lowest, while cases suffering from general paralysis do not present the change so markedly as might be supposed.

1.	Dementia	77.7 per cent.
2.	Chronic melancholia	76.4 per cent.
3.	Chronic mania	66.6 per cent.
4.	General paralysis	65.7 per cent.
5.	Idiocy and imbecility	29.6 per cent.
6.	Epilepsy	22.2 per cent.

2. The disease is much more frequent in the female sex, in whom it occurs at an earlier age than in the opposite sex. 3. It is comparatively rare before the ages of 45 or 50, except in general paralysis, where it is oftener met with at a younger period, especially in women. 4. It is essentially a morbid change which occurs in late middle life and old age. 5. It is not a marked pathologic condition in the male sex, who suffer from general paralysis. 6. It is seldom present in epilepsy.

The figures also show that in cases of dementia fragility of the bone is more marked than in other forms of mental disease, occurring in nearly one-half the cases. Smith discusses the histology, pointing out the changes that occur and showing that there are well-marked evidences of gross lesions in the posterior spinal ganglia, sensory roots and the peripheral nerves, and that probably the lesions in the mixed nerves are due to degeneration of the sensory fibers. These nervous conditions remove the trophic influences of bone formation. Minerals are carried away faster than they are deposited and the haversian spaces first suffer, being nearest the blood stream. The change beginning in the normal loose cancellous tissue gradually involves the more superficial dense bone until the whole thickness becomes porous and fracture is likely to occur.

15. **Mental Defect in Children.**—The forms of mental defect noticed by Shuttleworth are sexual erethism in children of the neurotic type, obsessions which are sometimes marked, hysteria, which is not recognized by the English authorities as much as it should be, phobias, etc. These observations were made while examiner of children for admission to special instruction schools of the London School Board and were extensive. He does not touch on the recognized insanities of children, but just alludes to the symptomatic and transient mental defects found in cases of chorea, probably of toxic origin. He remarks that in some cases not obviously cretinoid, benefit is obtained by the administration of thyroid, the more active metabolism producing increased and more regular brain action.

22. **Typhoid Perforation.**—Armour gives the history of the treatment of typhoid perforation and the statistics of its incidence and mortality, and calls attention to the fact that there is no pathognomonic sign, though Cushing has recognized a sort of preperforative stage, and there is apt to be a condition of gradual aggravation before complete severe peritoneal infection is attained. A rapid drop of temperature is not infrequent, and Dieulafoy regards it as almost an invariable sign. Rigor may be an early symptom. The value of leucocytosis is not yet positive, and to obtain its value a systematic examination of the blood from the beginning should be made in every case of typhoid fever. The diagnosis is often between typhoid fever and appendicitis. Perforative appendicitis is not so very frequent, according to Osler, though Cushing thinks it is commoner than generally supposed. The percentage of recoveries has greatly increased since the first operations some twelve years ago. The only treatment is surgical. The operation for typhoid perforation does not differ from that undertaken for intraperitoneal perforation from other causes.

24. **The Circulation of the Tissue Fluid in Man.**—Oliver experimented by taking a sample from the first easily flowing drop derived from near the root of the nail, the object being to obtain the actual proportion of lymph present in the tissues around the puncture. From his experiments he concludes that the amount of tissue lymph varies at different times in the day. Ingestion of food produces a rapid flow of lymph into the tissue spaces, the digestive curve always following the same general type with rapid rise, short acme and a gradual subsidence. There is a corresponding rise and fall in the percentage of corpuscles, hemoglobin and specific gravity of the blood. The facts suggest that when the body is in a state of rest the fluid exuded into the tissue is mainly absorbed directly into the blood and a to-and-fro transference from the capillaries to the tissue spaces, interposed as it is between the capillaries and lymph vessels, is called by Oliver the intermediary circulation. In normal individuals at certain times of the day there was apparent withdrawal of the tissue fluid. Oliver thinks that the inquiry has in part confirmed the opinion that goutiness primarily depends on the retention of some waste products, whether uric acid or something else. How gout originates may be a question, but how it is maintained when established is not doubtful in his opinion. It is essentially dependent on a derangement of the intermediary circulation, and the tissues themselves are the area in which gouty disturbances develop and manifest themselves. The residue may accumulate and be deposited in the tissues because their removal is prevented either by excessive capillary blood pressure or by a diminishing of that pressure reducing the fluid exchange between the blood and the tissues. Hence the two leading types of gout that are recognized. The inquiry is still in progress.

26. **Immunization of Animals to the Typhoid Bacillus.**—The following are the conclusions reached by Shaw:

1. The best method of obtaining a typhoid toxin is by the digestion of the bacilli. 2. This product is toxic. 3. This product can excite a reaction in susceptible animals, during which they develop immunity to the injection of living typhoid bacilli, and the serum from such an animal can protect another animal against typhoid infection. 4. The injection, intravenously, of living typhoid bacilli may result in the production of a "negative phase" of resistance.

38. **Streptococcus Infection of Intestines.**—Nobécourt analyzes the various cases of streptococcus infection of the intestines that have been published, from Beck's case in 1892 to Durante's recent communications, showing the large share of the streptococcus in infantile enteritis. The intestinal affection has been described variously as resembling cholera nostras, dysentery and typhoid, and Booker found streptococci in 27 out of 92 cases of gastro-enteritis characterized by high fever and by the presence of numerous mononuclear and polynuclear leucocytes in the diarrheic stools, with red corpuscles and mucus. Streptococcus enteritis is particularly severe in adults. Only 5 recovered out of 12 cases reported by Tavel and 4 of these had presented the typhoid form. The others were more of the type of septic pyemia or fulminating cholera nostras. In children the streptococcus is liable to induce a dyspeptic, catarrhal

type, infantile cholera, follicular enteritis, acute enterocolitis with severe symptoms (Hutinel's "dry cholera"), or a chronic gastro-enteritis. Symptoms on the part of the stomach are frequent and severe, as also buccopharyngeal lesions. Secondary bronchopulmonary affections are more frequent in the hospital than in general practice. Nephritis and cystitis may also occur, with erythemata, and meningeal symptoms are not infrequent. Other complications that have been observed are peritonitis, pleurisy, pericarditis, icterus and otitis. None of these manifestations are pathognomonic of the underlying streptococcus intestinal affection, and the lesions induced are not specific, although the streptococci seem to have a special predilection for the follicular apparatus.

43 La legislation antialcoolique de l'état d'Iowa. F. Munch.
44 (No. 39.) *De l'origine des néoplasmes malins. F. de Quervain.

42. Experimental Study of Action of Sodium Chlorid on Kidney Epithelium.—Castaigne and Rathery have been experimenting *in vitro* with saline solutions of varying density and found that all solutions above and below a specific gravity of .78 C. were distinctly injurious to rabbit kidney tissue, actually dissolving it. The salt solution is not *per se* nephrolytic, but the osmosis must be identical with that prevailing in the kidney tissue. They then studied the effect on the rabbit organism of deprivation of salt and supersaturation. They have become convinced that the salt solution which filters through the glomeruli has a constant osmotic tension in physiologic conditions, similar to what has been established in regard to the blood and cerebrospinal fluid. When the kidney is sound, as more or less salt is ingested and eliminated through the kidney, more or less water comes with the salt, thus maintaining the constant specific gravity unless the intake is unusually large. The glomeruli are protecting filters which spare the renal tissue from the nephrolytic effect of a too concentrated or too diluted saline solution. The kidney tissue is protected against the effect of an injurious saline solution by the special arrangement of the protoplasm which these writers call the "brush border"—*bordure en brosse.* This border disappears in epithelial nephritis and the loss of this protecting device renders the kidney more sensitive to the variations in the osmotic tension of the fluid issuing from the glomeruli. Briefly transient variations pass without causing disturbance on account of this protecting device, but when the kidney tissue is diseased, variations in the osmotic tension entail severe injury. Lesions were found in the kidneys in every cadaver in which polyuria was known to have existed during life, and lesions were found in the rabbits every time polyuria had been experimentally induced for a certain length of time. Albuminuria developed invariably in the animals deprived of salt, and it also appeared in a subject placed on a salt-free diet who had previously shown no evidence of renal derangement. On the other hand, deprivation of salt had an unmistakably favorable action on a number of patients with pronounced nephritis, considerable edema and albuminuria. Salt administered to rabbits in small amounts did not induce albuminuria, but when continued beyond a certain limit, or larger amounts were given, albumin appeared in the urine in every instance, whether the salt was injected or ingested per os. The effects were more marked as the kidneys of the animals were more inclined to be diseased. Injections of salt solution so small as to cause no appreciable effects in healthy animals produced serious and sometimes fatal manifestations on the part of the kidneys in animals already affected with kidney lesions. Clinical experience to date has shown that in subjects with interstitial nephritis without albuminuria or a specially fragile epithelium, the alimentary salt test causes merely transient albuminuria. In subjects with Bright's disease and edema, the alimentary salt test continued for several days increases the albuminuria and the edema. Fatal uremic manifestations have been observed after infusion of large amounts of artificial serum in patients with slow, atrophying nephritis.

44. Origin of Malignant Neoplasms.—De Quervain reviews the wealth of literature published on this subject of late, and remarks that the assumption of a parasitic origin for cancer far from settling all difficulties raises a host of new problems. He thinks that the various explanations of the origin of these neoplasms offered to date are none of them sufficient, and that further research along all lines is required. He suggests that the prospects are brighter for this research in the line of the transmission of cancer from animal to animal. The first question to be solved is whether the cancer is transmissible by the cancer juice alone, strictly excluding all the cancer cells. As we learn the true nature of the transmitting virus, the study of the subject will be facilitated. He adds that in any event further researches must be conducted with the application of critical judgment which seems to have been lacking in much of the experimental work that has been done, which has resulted in parasite discoveries as numerous as the parasites have proved ephemeral.

49 *Spreading of Carcinoma in Parametrium. R. Kundrat (Werthelm's clinic, Vienna).—Ueber die Ausbreitung des Karzinoms im parametranen Gewebe bei Krebs des Collum uteri.
50 *Ueber Hyperemesis gravidarum mit Aufstellung einer neuen Intoxikations-Theorie vom Wesen der Krankheit. C. Behm (Berlin).
51 *Ueber die Bedeutung des Lig. rotundum uteri bei Herniotomien. F. Kayser (Gusserow's clinic, Berlin).

45. Syphilitic Changes in Cord.—Bondi found arteritis or phlebitis in the umbilical cord in 15 out of 31 cases of certain syphilis and 4 other probable cases. The process was always inflammatory with exudation. In 100 other cases, free from any taint of syphilis, no evidences of inflammation could be detected in the cord.

46. Delivery with Contracted Pelvis.—Wolff states that there have been 581 cases of delivery with contracted pelves during the last ten years at the Berlin Charité. In 297 the conjugata vera was 9.75 cm. or less in diameter and birth occurred with head presenting. In 99 it proceeded spontaneously, and in 161, forceps were applied; high forceps in 71 cases, 14 times ineffectually. In 51 the head had to be perforated. Prophylactic version and high forceps are valuable aids for reducing fetal mortality, but craniotomy is still indicated in certain cases. One of the patients was a woman with a conj. vera of 7.5 cm. who was delivered twelve times in the clinic. Four times craniotomy was necessary with head presentation; seven times delivery was accomplished by version and extraction. Four of the children were delivered alive.

47. Obstetric Statistics.—Bucura states that the total puerperal mortality in Chrobak's service among the 23,639 maternity cases for the last seven years has been 2.79 per cent. As there are from 8 to 18 births a day and only one bath tub in the receiving room the full bath has been supplanted by washing the patient with running water as she lies in a shallow tub, cleansing the external genitalia with 1 per 1,000 sublimate, never douching the vagina in healthy women. In 6,505 non-operative births, morbidity was 10.05 per cent., and mortality 1.2 per 1,000. In 161 operative cases the morbidity was 27.3 per cent. and the mortality 35.6 per 1,000. The morbidity of those examined and operated on in the clinic was 23.02 per cent. and the mortality 16.45 per 1,000, while those who had been examined before entering the clinic showed a morbidity of 32.3 per cent. and mortality of 56.1 per 1,000. Stroganoff was the first to insist on the advantages of bathing the woman under running water instead of in a full bath, and thinks that this is the cause of the reduction of his morbidity from 15 to 7 per cent. Bucura's article fills thirty-four pages.

49. Spreading of Carcinoma of Cervix.—Kundrat found the parametrium involved in 44 out of 80 cases in which the uterus had been removed on account of carcinoma of the collum. The connective tissue between the parametrium and the regional

lymphatic glands and the lymph passages in the connective tissue were always found intact even when the regional lymphatic glands themselves were carcinomatous. He examined 21,000 sections under the microscope and gives the particulars of the 80 cases. In 22 the parametrium was intact, and in 8 the glands were invaded while the parametrium was intact; in 18 both were involved. In only 2 were the lymphatic vessels carcinomatous.

50. **Hyperemesis Gravidarum.**—Behm suggests that this condition may be due to intoxication of the maternal blood, proceeding from the periphery of the ovum, probably of a syncytial nature. He treated 6 cases on this assumption, flushing the rectum with .6 per cent. salt solution at 28 to 30 C., using four to six quarts a day. Two were severe cases and all recovered with such promptness as to confirm him in this assumption of intoxication and relief by flushing the system.

51. **Round Ligament in Herniotomies.**—Kayser found that previously unknown retroflexion has developed after radical operations for hernia. He thinks that injury of the round ligament may have something to do with the retroflexion, and consequently advises isolating and fastening this ligament in the abdominal ring when operating for an inguinal hernia on a female subject, being careful not to shorten the ligament.

61 Genuine Cysts in Long Bones. C. Beck (New York).—Ueber echte Cysten der langen Knochen.

53. **Simple Inflammatory Strictures of Large Intestine.**—One of the 3 cases described simulated carcinoma, but proved to be a cicatricial stricture resulting from a diffuse ulceration of the mucosa of the colon of unknown origin. In another case there had been suppuration in a false diverticulum with secondary stenosis of the flexure. The third case was consecutive to appendicitis. The symptoms had simulated a tuberculous intestinal trouble. The patient recovered after resection of the lesion.

54. **Intestinal Occlusion.**—Philipowicz noted volvulus of the sigmoid flexure in a third of his 98 cases of ileus observed at Czernovitz. The disturbances were due more to the strangulation induced than to the torsion *per se*. Torsion of 180 degrees was liable to cause greater disturbance if tight, than in other cases with torsion of 360 degrees. The latter was tolerated for days by certain patients without serious injury of the intestines when the strangulation was not pronounced. In 5 patients he was able to reduce the torsion by inserting the rectum tube without operative intervention. In others he succeeded in evacuating the contents of the twisted loop by this means, but the flexure became redistended, showing that the torsion still persisted and an operation became necessary. On account of the liability to recurrence he always fastens the loop after reducing the torsion so that it can not occur again. He reviews his extensive experience with ileus in detail, tabulating the cases in twelve groups.

58. **Technic of Treating Congenital Fistula of Neck.**—Kocher believes that Hacker's method of turning the end of the fistula wall over inside like the finger of a glove, and suturing the mucosa above it, is not applicable to every case on account of the difficulty of mobilizing the walls of the fistula sufficiently for the purpose. He recommends another method which is applicable to all cases. The fistula walls are mobilized as much as possible, then a large sound is inserted in the outer opening of the fistula and pushed in until it protrudes in the mouth, pushing up the mucosa in front of the lower front edge of the tonsil. The mucosa is then incised. Then the lower end of the fistula opening is fastened to the sound and drawn through with the latter into the mouth where it is sutured and cut off short. Nothing is left then of the fistula except a short, open passage under the mucosa of the mouth, passing around the tonsil, both ends opening into the mouth. He found Hacker's method useful in obliterating an incomplete internal anal fissure resulting from an abscess due to actinomycosis. He mobilized and drew out into the rectum the head of the fistula, then turned it back inside the fistula, and sutured the rectal mucosa over it. The article is illustrated.

59. **Origin of Hare-Lip.**—Haymann found the hand of the fetus in the cleft in a case described, held there by an amniotic cord formation. The child presented several other deformities. After going over the subject carefully he thinks that we have no ground for assuming an amniogenic origin for hare-lip. He also reviews the heredity of such deformities. He found heredity noted in 20 per cent. of 244 cases on record. In one family hare-lip recurred through four generations.

67 *Injuries of Tongue-Shaped Process of Upper Tibial Epiphysis. C. Schlatter (Zurich).—Verletzungen des schnäbelformigen Fortsatzes der oberen Tibia-Epiphyse.
68 Recovery After Operation for Traumatic Hernia of Diaphragm. O. Riegner (Breslau).—Eine traumatische Zwerchfellhernie.

62. **Injuries of the Skull and Fate of the Injured.**—Brun's article is completed in this number. It contains 200 cuts and is a most exhaustive study of the subject from every point of view, based on 404 cases observed at Krönlein's clinic at Zurich. The primary and secondary disturbances are particularly noted, as well as the symptoms of apathy, disturbances in memory, vertigo and headache. The literature on the subject is also extensively reviewed. The cases are classified and each group is studied separately.

63. **Dermoid Cysts and Teratomata in the Mediastinum.**—Dangschat has observed 2 cases and reviews 42 others he has found in the literature. Without operation the prognosis is absolutely bad. Only 13 out of the 44 were operated on and total extirpation of the cyst was possible only once. In 3 cases the fatal termination followed soon after the intervention; in one instance it was due to hemorrhage from the mammary vein. When extirpation is not possible, the cyst should be evacuated and sutured to the skin. In 19 cases symptoms of the tumor had been noticed for two to several years. The growth is much slower than that of malignant tumors, and the latter seldom appear before the age of 30, while these tumors usually make their presence known before this age. Out of 29 cases pains in the thorax had been noted in 9, and in the shoulder, head and ear in 3. Difficulty in breathing was the most frequent symptom and sometimes the only one for years. One patient had been troubled with this symptom for 44 years, dying at 60 from the progress of the lesion. Discovery of hair in the sputum is the only pathognomonic sign. It was found early in 3 cases. In 2 there were no symptoms of any kind.

66. **Articulated Plaster Casts.**—Lieblein urges more general use of hinged plaster casts for the treatment of congenital and acquired deformities. He considers them indispensable for the treatment of club-foot, especially in adults. He describes the technic of making and applying them and gives radiograms of the progress attained.

67. **Injuries of Tongue-Shaped Process of Upper Tibial Epiphysis.**—Schlatter gives radiograms of 7 cases in which this process was injured in male subjects, all but one affecting the right side. The pain on pressure is typical. An immobilizing dressing with early massage of the muscles of the thigh will aid in the cure.

80 Einige Hände-Desinfektions-Versuche. Engels (Marburg).

69. **To Differentiate Bacteria.**—Onelianski describes a new culture medium made of phenolphthalein, sodium formate and agar. The bacteria stain differently on this medium and it is possible to differentiate readily the colon, typhoid, diphtheria and pseudodiphtheria germs.

70. **To Test Agglutination of Tubercle Bacilli.**—Köppen treats the bacilli with caustic potash solution, thus saponifying them. The stem fluid he uses for the agglutination is milky and homogeneous and does not become putrid, thus not requiring an antiseptic ingredient. After this saponification the tubercle bacilli take the stain as readily as before.

72. **Bacteriology of Whooping Cough.**—Jochmann found the *Bacillus pertussis* (Eppendorf) in 20 cases of pneumonia complicating whooping cough. As this bacterium is so similar to the influenza bacillus, he suggests that attention had better be paid to the presence of cases of influenza in the environment of children with whooping cough.

73. **Yeast in Experimental Infections.**—Turro found that yeast had an unmistakably favorable effect in cases of experimental streptococcus infection in rabbits, both local and general. He asserts that it was possible to confer temporary immunity to both streptococcus and staphylococcus infection by subcutaneous injection of the yeast.

81 (XXX, No. 39.) *Ogston's Operation for Club-Foot. C. Lauenstein (Hamburg).—Zu Ogston's Operation des rebellischen Klumpfusses.

81. **Club-Foot.**—Lauenstein advocates Ogston's method of enucleating the bony kernel. He finds it is easily performed but should be preceded by an *x*-ray examination. What bones are to be operated on must be determined by the operator in each individual case. It is not specially important whether the wounds of the soft part are sutured after operation or not, if sufficient portions of the bony kernel have been removed. The remedying of the condition is very easy and complete. Besides the equinus and varus types any inward bending of the foot is easily relieved. The after-treatment is notably shortened and the danger of disturbance to the growth of the foot is not to be dreaded. (The technic of Ogston's operation was described in THE JOURNAL, xxxix, p. 110, 1902.)

83 *Ein Ligamentum suspensorium fundale medium nach Ventrifixur. F. Michel.
84 *Treatment of Apparent Death of the Newly Born. W. Zangemeister.—Ueber die Behandlung des Scheintodes Neugeborener.

83. **Ligamentum Suspensorium Fundale Medium.**—Michel adopts this name proposed by Fritsch for a formation which sometimes follows ventrofixation of the uterus, viz., a fibrous cord extending between the fundus and the parietal peritoneum. In the course of years this may reach several centimeters in length, and he gives an account of a case, with illustration, where it was 15 cm. long. He remarks that such a condition may have uncomfortable results for the patient, as was the fact in the case reported, and recommends that in ventrofixation one should not make a limited attachment of the fundus to the peritoneum, but make a much more thorough fixation.

84. **Treatment of Apparent Death of the Newly-Born.**—Zangemeister remarks that the attempts to apply the inhalation of oxygen as a therapeutic measure have not been very satisfactory as a general thing, but there is one condition in which it is proving extremely valuable. This is in severe asphyxia neonatorum. The almost invariable success and the rapidity of its action, with no inconveniences, render it a most valuable aid in this emergency. He uses a thin-walled rubber bulb filled from a small portable tank of compressed oxygen. The oxygen is forced through a tracheal catheter into the infant's lungs by gentle, regular pressure on the bulb. When the lungs have become distended he applies gentle external pressure to the thorax. The air escapes along the outside of the catheter, which must be of small diameter to allow this. The lungs are then inflated again by gentle pressure on the bulb and emptied as before, and these procedures are repeated continuously as long as required. The prompt reddening of the skin shows the favorable action of the oxygen. It can be applied while the infant is in a warm bath. The narcosis from carbon dioxid is dispelled in this way more rapidly than by any other means and the stimuli applied become more promptly effectual.

89 *Kastration wegen funktionierender Ovarien bei rudimentärer Entwicklung der Müller'schen Gange. Ibid.
90 *Beitrag zur Pubiotomie nach Gigli. P. Baumm (Breslau).

86. **Apparent Extra-uterine Gestation in a Rabbit.**—In Kamann's rabbit the placenta was found attached to the greater omentum with a long twisted pedicle of omentum tissue and vessels. He considered it a case of abdominal gestation and as such exhibited the specimen at his local medical society. Further investigation, however, revealed a cicatrix in the wall of the uterus and evidences that the uterus had been the original seat of the fetus but that the latter had escaped into the abdominal cavity in consequence of rupture of the uterus, still enclosed in its intact membranes, and that a connection between the latter and the omentum had occurred secondarily.

87. **Prophylaxis of Gynatresia.**—Pincus thinks that the vagina may become obliterated or obstructed in consequence of gonorrheal infection during birth or during other severe infections later in which the vaginal mucosa may share in the inflammation. He advocates systematic investigation of the permeability of the vagina in new-born infants. It can be done with the sound in the absence of gonorrhea, and in case of the latter infection the vulva and vagina should be appropriately treated. The pains and tempestuous onset of menstruation in case of gynatresia may entail a severe shock to the nervous system. He adds that it is important to instruct growing girls approaching menstruation and to inquire after children's diseases in persisting amenorrhea. In molimina with vicarious hemorrhage and in case of preceding severe disease, he urges careful examination for possible gynatresia. Stagnating blood may prove a culture medium for germs and the source of virulent infection later.

88. **Vaginal Pan-Hysterectomy Without Narcosis.**—Gradenwitz reports 3 cases of total extirpation without narcosis. One was on account of retroflexio with obstinate hemorrhage, phthisis and anemia; another for total prolapse of the uterus and vagina in a subject with a large struma, and the third

on account of carcinoma of the portio accompanying severe degeneration of the heart. The latter patient succumbed in shock. The only painful steps in the operation were the ligation of the lower parts of the broad ligaments and tubes. In one case anesthesia of the broad ligaments was first induced with Schleich's solution, and in another it was used for the plastics of the perineum. He injected a syringeful of 1 per cent. morphin fifteen minutes before operating.

89. **Functioning Ovaries with Rudimentary Development of Mueller's Duct.**—Gradenwitz relieved a patient who suffered from violent pains every four weeks, without further evidences of menstruation, by ablation of the rudimentary uterus bicornis and ovaries, the latter being in cystic degeneration. Complete recovery. In 23 similar cases on record all were cured by operation, with 2 exceptions, one succumbing to sepsis.

90. **Adverse Criticism of Gigli's Pubiotomy.**—Baumm followed Gigli's technic for extramedian symphyseotomy in 2 cases and his experience was very unfavorable. The bleeding was more severe than in cases operated on in the mons veneris, and in both instances the vagina and bladder were lacerated. The abundance of blood in the cut ends of the bones also complicated the wound. Both patients succumbed to sepsis.

100 *Study of Heredity. E. Schwalbe.—Das Problem der Vererbung in der Pathologie. (Commenced in No. 36.)

91. **Cancer Statistics at Munich.**—Bollinger's statistics for fifty years show that the proportion of deaths from cancer has paralleled the growth of the population and not exceeded it as in most cities. He mentions as an argument against the assumption of an infectious origin for cancer the rarity of its occurrence under the age of 15. This is directly the opposite of what is observed in case of infections in general.

92. **Acanthosis Nigricans.**—The 2 cases reported from Marburg by Hess bring the number on record to 40. Treatment has been only symptomatic to date except in Spietzka's patient, the ablation of a malignant deciduoma being followed by complete subsidence of the affection in this case.

93. **Prevention of Postoperative Cystitis.**—Baisch describes the method of preventing postoperative cystitis which has been adopted at Döderlein's clinic at Tübingen with complete success. He defines the affection as a bacterial inflammation of the bladder developing consecutive to operations in which the innervation or nutrition of the bladder has suffered and catheterization is necessary. It is impossible to prevent the entrance of germs in all cases, and it is likewise impossible to refrain from injury to the bladder in many instances. The use of the catheter is avoided to the utmost possible extent, but if absolutely required, the bladder is stimulated to extra secretion by injection of glycerin. The evening after the operation, if the patient has not urinated spontaneously, he injects 20 c.c. of a 2 per cent. glycerin solution of boric acid. A Nélaton catheter is first introduced, and as soon as the first drops of urine make their appearance the syringe is applied and the borated glycerin slowly injected into the full bladder. Usually in less than five to ten minutes the patient experiences a desire to urinate spontaneously, and the evacuation of the bladder is not followed by any after-effects. No inconveniences have been observed in any case. It was not necessary to repeat the injection except in the rarest cases, generally after anterior colporrhaphy. The bladder is injured to such an extent in a Wertheim abdominal operation for cancer of the uterus that it is not able to respond to this stimulus. In these cases the inevitable catheterization is followed each time by rinsing out the bladder with 500 c.c. of a 3 per cent. solution of boric acid. By these prophylactic measures postoperative cystitis has been warded off in nearly every instance. If no effect is derived from the glycerin injection, it is followed in an hour by catheterization with the disinfecting rinsing immediately afterward. The rinsing procedure should be repeated as long as the catheter is needed, until urination has become spontaneous and complete.

94. **Radioscopy of Peristalsis.**—Lommel describes his experiments with docile dogs fed with chopped meat mixed with bismuth and fastened so that the *x*-rays could be passed through them at the most convenient angle. Two minutes after ingestion of milk rhythmic wave movements could be seen in the greater curvature. Ten complete peristaltic waves almost invariably corresponded to 120 seconds in all the animals. The latter were not fatigued nor pathologic from application of fistulas, etc., so that the peristalsis observed could be regarded as entirely normal. Application of warmth to the stomach and abdomen did not materially modify the number or velocity of the waves, but it was noted that the waves were smaller at the beginning than in the control animals. The pylorus opened a little earlier in some of the animals that had been treated with warmth, than was noticed in the controls. Application of cold had no appreciable effect on the movements of the stomach nor on the opening of the pylorus. Administration of somatose accelerated the stomach digestion, increasing the rhythm so that ten waves were counted in 105 to 110 seconds, instead of in the normal 120. Meat extracts had a similar but even more pronounced action, accelerating the rhythm to ten waves in 100 seconds. Whether this stimulation of the rhythm means an actual acceleration of the stomach digestion is not revealed by the *x*-rays. So much bismuth clings to the walls of the viscus that the final evacuation of the stomach passes unperceived. His researches established another point, namely, that emotion, psychic factors, have a far greater influence on the stomach peristalsis than physical or chemical factors. Again and again he witnessed that animals not accustomed to laboratory maneuvers, which were frightened and depressed, did not show any signs of waves nor evacuation of the stomach, sometimes for two and three hours, but so soon as they were released, marked peristalsis could be seen, soon followed by the emptying of the stomach. Docile, trusting animals showed peristalsis in less than ten minutes after the experiment was commenced, the stomach emptying in forty to fifty minutes. By intentionally annoying or depressing the docile, well-trained animals, it was possible to delay or completely arrest the stomach peristalsis, delaying the emptying of the stomach past two or three times the normal period of digestion. He thinks these results demonstrate that the human stomach is capable of being profoundly influenced through the psyche, probably more profoundly than by many of our therapeutic measures. Interesting phenomena were noted in respect to the intestinal peristalsis. The *x*-rays showed unmistakable antiperistaltic movements, and a distinct periodicity in the emptying of the stomach and the peristaltic movements of the intestines. During the pauses after energetic peristalsis the emptying of the stomach was also temporarily suspended, the stomach resting with the intestines and resuming activity with them.

97. **Treatment of Abortion.**—Nassauer illustrates a forceps for emptying the uterus in case of abortion, which he claims can be used by the general practitioner without fear of injury. The tips form thick, oval spoons, the edges of which are so broad and rounded that perforation of the uterus wall is impossible.

98. **Two-Part Centrifuging Tube.**—Napp's tube is shaped like the ones ordinarily in use, but the tapering end below is cut off a short distance from the point and a cap of the same size fits tightly over it. The fluid above can be poured off after centrifuging and the cap below removed. Even the smallest amount of sediment can then be easily taken out of this conical cap.

100. **The Problem of Heredity in Pathology.**—Schwalbe reviews recent researches and theories, and remarks that ex-

periences in pathology so far afford no data for the assumption of inheritance of acquired properties. Neither do they sustain Weismann's theory, or rather they do not confirm it. Its proof must be sought in other sources than pathology; it is neither overthrown nor confirmed by what we know of pathologic heredity.

102. Diagnosis of Catarrhal Form of Pyelitis.—Favitzky reviews the details of 14 cases of catarrhal pyelitis, endeavoring to prove that it is possible to differentiate this form of kidney affection from others. The pains, composition of the urine, variations in the sediment and specific gravity are not pathognomonic, but they suggest the catarrhal form as they continue with periodical febrile exacerbations and periodical changes in the urine.

103. Differential Value of Oliver's Sign in Aneurism of Aorta.—This sign is the upward movement of the larynx, synchronous to the cardiac systole, which Oliver announced was encountered in subjects with aneurism of the arch of the aorta. Drozdovsky states that he noted this sign in a number of cases of aneurism of the aorta, but found it equally marked when the aneurism was located at other points of the thoracic aorta than the arch. He gives the clinical history of 9 cases.

106. Heredity of Cancer and Trauma as a Factor.—Geinatz rejects the theory that cancer can be inherited. He found no history of cancer in the family in 192 out of 210 cancer patients. Only 18, that is, 8.6 per cent., reported previous cases of cancer in the family, and in only 7 of these the father was mentioned and in 1 the mother. In the other 10, more distant relatives had been the cancer subjects. In only 2 did the cancer affect the same organ as in the other member of the family. In 3 cases cancer had occurred several times in the same family. [In an article recently published in the *Vratchebnaya Gaseta*, Nos. 13-16, Geinatz announces that among 1,906 cases of various neoplasms he found there had been a preceding trauma at the spot in 233 cases. The largest proportion of tumors with a history of preceding trauma was observed in the neuromata, 38.5 per cent. of which had followed a trauma. In the 233 cases of tumors with preceding trauma, sarcomata took the lead with 20.3 per cent.; then came carcinomata with 15.1 per cent.; the mixed neoplasms, chondromata, endotheliomata and myxomata, with 8.6 per cent., and lastly, the benign neoplasms with 5.4 per cent. The trauma had been single in 87.9 per cent., and the skin had not been broken in 27.4 per cent. of the total number of cases of cancer. The interval between the trauma and the first signs of the cancer ranged from six weeks to two years in the 75 cases in which this point could be ascertained, with 9 exceptions in which the interval was longer than two years. In the 716 cases of benign tumors, preceding trauma was noted in 5.4 per cent., and in 92.4 per cent. of these the trauma had been single. In 30.7 per cent. there had been solution of continuity. He thinks that these facts indicate that trauma certainly affords a predisposition for tumor formation, although it does not of itself cause the subsequent neoplasm.—Ed.]

107. Transitional Forms of Rheumatism and Pyemia.—Byelogolovy regards articular rheumatism as a mild form of pyemia, and cites a number of instances of transitional forms to sustain this assumption.

109. Amyloid Kidney.—Favitzky concludes in this number his comprehensive study of 7 cases of amyloid kidney. He gives in tabulated form the various symptoms and condition of the organs. The liver and spleen were enlarged in some and not in others. The amount of urine in 3 cases averaged 2,300, 3,700 and 1,900 c.c. in the twenty-four hours, and in the others ranged from 200 to 1,000 c.c. Albuminuria was noted in all, averaging 2.5 to 3.2 per cent.

110. Operation for Retroflexed Uterus.—Alexandroff puts a suture through the rear edge of each broad ligament a short distance from its attachment to the uterus. He then draws the edges together over the uterus and fastens them in contact with a stitch above and below. The results in 4 cases have been excellent. He illustrates his technic.

111. Artificial Fertilization of Mammals.—Ivanoff's experiments were conducted at first on guinea-pigs, rabbits and dogs, but proved so successful that he included horses and cows in his research as also sheep, mice and birds. The results have established the possibility of fertilizing mammals with semen in an artificial medium entirely free from the secretions of the male sexual accessory glands (prostate, seminal vesicles, etc.). The practical results of this research have already been adopted to some extent in stock-raising in Russia. Most remarkable results have been obtained in this way in cross-breeding and the production of hybrids. He has found that the psychic condition of the female animal and the excitement connected with copulation have nothing to do with successful conception nor with the determination of the sex of the offspring. In fact, conception occurs more regularly with artificial than with natural fertilization when it is systematically conducted, utilizing the most favorable seasons of the year and the heat of the animals. Every one of his experiments on horses in the spring of 1901 resulted positively. Artificial fertilization is thus a powerful means of combating sterility in brood animals. The spermatozoa are equally lively and capable of fertilizing the ovum whether they are suspended in the secretions of the prostate and seminal vesicles or in physiologic salt solution or in Locke's fluid or in any weak alkaline solution. The spermatozoa retain their fertilizing power for twenty-four hours after the death of the animal. It is not necessary to introduce them directly into the cervix; a large number of experiments resulted positively with the spermatozoa placed merely in the vagina. The young conceived and born under these conditions developed normally in every respect, without the slightest apparent deviation from the standard type.

114. New Parasite Found in Sarcoma in Stomach.—Kulesh describes a sporozoön to which he ascribes etiologic importance, He gives good illustrations of it and shows that it develops at the expense of the juices and tissues of its host, with an extracellular and intracellular dual life cycle.

117. **Alkalinity of Blood in Leucocytosis and Infections.**—Orlovsky's comprehensive researches on dogs and human beings, sick and well, all resulted negatively, confirming his previous announcements that the alkalinity of the blood is not proportionate to the number of white corpuscles, but is an almost constant phenomenon through the most diverse conditions, varying very slightly from normal at any time. The only exceptions to this rule are in advanced stages of cachexia from cancer, uremia or diabetes. The blood retains its normal alkalinity during infections until they become very virulent, when it gradually declines, usually an almost agonal phenomenon.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. For Practitioners and Students. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry and the Kindred Branches, Including Much Collateral Information of an Encyclopedic Character, Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Micrococci, Streptococci; Eponymic Tables of Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc., etc. By W. A. Newman Dorland, A.M., M.D., Editor of the "American Pocket Medical Dictionary." Third Edition, Revised and Enlarged. Flexible Leather. Pp. 798. Price, $4.50 net; with Thumb Index, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

PHYSICS AND INORGANIC CHEMISTRY. A Manual for Students and Practitioners. By Alexius McGlannan, M.D., Associate Professor of Physiologic Chemistry, Instructor in Clinical Laboratory, College of Physicians and Surgeons, Baltimore, Md. Series Edited by V. C. Pedersen, A.M., M.D., Instructor in Surgery and Anesthetist and Instructor in Anesthesia at the New York Polyclinic Medical School and Hospital. Illustrated with 20 Engravings. Cloth. Pp. 216. Price, $1.00. Philadelphia and New York: Lea Brothers & Co.

A TEXT-BOOK UPON THE PATHOGENIC BACTERIA. For Students of Medicine and Physicians. By Joseph McFarland, M.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia. Fourth Edition, Revised and Enlarged and Entirely Reset. Fully Illustrated; a Number in Colors. Cloth. Pp. 629. Price, $3.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A TEXT-BOOK OF PATHOLOGY. By Alfred Stengel, M.D., Professor of Clinical Medicine in the University of Pennsylvania. With 394 Text Illustrations, Many in Colors, and 7 Full-page Colored Plates. Fourth Edition, Revised and Enlarged. Cloth. Pp. 933. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A TEXT-BOOK OF OBSTETRICS. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania. With 746 Illustrations; 39 of Them in Colors. Fourth Edition, Revised and Enlarged. Cloth. Pp. 900. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA (State Board of Health). Organized 1847. Meeting of 1903. Talladega, April 21-24. Cloth. Pp. 553. Montgomery, Ala.: Brown Printing Company. 1903.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, Oct. 3, 1903:

Borden, William C., major and surgeon, is detailed to represent the Medical Department of the Army at the annual meeting of the Mississippi Valley Medical Association, to be held at Memphis, Tenn., October 7, 8 and 9.

Glennan, James D., major and surgeon, in addition to his present duties, is detailed as professor at the Army Medical School in Washington, D. C.

Miller, Reuben B., first lieut. and asst.-surgeon, now at San Francisco, is relieved from further duty in the Division of the Philippines, and will report to the commanding general, Department of California, for assignment to duty.

Patton, Irvine W., first lieut. and asst.-surgeon, is relieved from further duty in the Division of the Philippines and from temporary duty at the Presidio, and will proceed to Fort Hamilton for duty, to relieve First Lieut. Walter D. Webb, asst.-surgeon, who will proceed to West Point, N. Y., and report at the U. S. Military Academy for duty.

Rafferty, Ogden, major and surgeon, will proceed from San Francisco to Seattle, Wash., and make a sanitary inspection of the transport *Dix*.

Truby, Willard F., first lieut. and asst.-surgeon, will proceed to West Point, Ky., and report to Major-General J. C. Bates for duty, and, on the completion thereof, will return to his proper station.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending Oct. 10, 1903:

Surgeon T. W. Richards, commissioned surgeon, with rank of lieutenant-commander, from March 3.

Asst.-Surgeon B. L. Wright, ordered to the Naval Hospital, Pensacola, Fla.

A. A. Surgeon F. A. Richardson, appointed acting assistant surgeon, with rank of lieutenant, junior grade, from September 29.

A. A. Surgeon W. N. McDonnell, ordered to the Naval Academy.

Surgeon D. N. Carpenter, commissioned surgeon, with rank of lieutenant-commander, from March 3.

Surgeon E. J. Grow, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *Mohican*.

Asst.-Surgeon C. N. Fiske, detached from the *Mohican* and ordered home to await orders.

A. A. Surgeon L. H. Schwerin, detached from the *Southery* and ordered to the *Yankton*.

A. A. Surgeon J. T. Miller, detached from the Navy Yard, Mare Island, Cal., and ordered to the Naval Hospital, Mare Island, Cal.

Pharmacist J. Cowan, detached from the Naval Magazine, Iona Island, N. Y., and ordered to Washington, D. C., for examination for retirement and then home to wait orders.

Surgeon E. H. Marsteller, detached from the *Panther* and ordered home to wait orders.

P. A. Surgeon J. C. Thompson, ordered to additional duty at the Navy Yard, Puget Sound, Washington.

P. A. Surgeon W. H. Bell, detached from the *Yankton* and ordered to the Navy Yard, Portsmouth, N. H., for additional duty on the *Southery*.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Oct. 10, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Sept. 27-Oct. 3, 3 cases.
California: Los Angeles, Sept. 20-26, 8 cases.
Illinois: Belleville, Sept. 27-Oct. 3, 3 cases.
Maine: Grant Isle, Oct. 2, 3 cases; Madawaska township, Oct. 2, 5 cases; Van Buren, Oct. 2, 2 cases.
Massachusetts: Cambridge, Sept. 27-Oct. 3, 1 case; Taunton, Sept. 27-Oct. 3, 2 cases.
Michigan: Port Huron, Sept. 27-Oct. 3, 3 cases.
Mississippi: Natchez, Sept. 20-26, 1 case.
Missouri: St. Louis, Sept. 29-Oct. 5, 1 case.
New York: Niagara Falls, Sept. 27-Oct. 3, 1 case.
Ohio: Dayton, Sept. 27-Oct. 3, 2 cases; Lorain, Sept. 27-Oct. 3, 1 case.
Pennsylvania: Altoona, Sept. 27-Oct. 3, 4 cases, 1 death.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Aug. 16-22, 1 case.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Sept. 12-19, 3 cases.
Brazil: Rio de Janeiro, Aug. 31-Sept. 13, 124 cases, 64 deaths.
Belgium: Brussels, Sept. 12-19, 1 death.
Canada: Quebec, Sept. 27-Oct. 3, 1 case.
Chile: Antofogasta, July 25-31, 20 cases, 9 deaths.
France: Paris, Sept. 12-19, 1 death.
Great Britain: Birmingham, Sept. 12-26, 15 cases, 1 death; Glasgow, Aug. 31-Sept. 25, 1 case; Leeds, Sept. 12-26, 24 cases; Liverpool, Sept. 12-26, 6 cases, 2 deaths; London, Sept. 12-26, 8 cases, 2 deaths; Newcastle-on-Tyne, Sept. 12-19, 16 cases.
Italy: Catania, Sept. 10-17, 1 death.
Mexico: City of Mexico, Sept. 13-27, 6 cases, 3 deaths.
Netherlands: Amsterdam, Sept. 20-26, 4 cases.
Russia: Moscow, Sept. 5-12, 2 deaths.
Straits Settlements: Singapore, Aug. 16-22, 1 death.
Turkey: Constantinople, Sept. 7-20, 3 deaths; Smyrna, Sept. 7-20, 118 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Sept. 28-Oct. 7, 105 cases, 2 deaths; Minera, to Oct. 3, 7 cases, 2 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Aug. 31-Sept. 13, 1 case.
Colombia: Panama, Sept. 21-28, 2 cases, 1 death.
Costa Rica: Limon, Sept. 18-24, 6 cases, 5 deaths.
Mexico: Nuevo Laredo, Sept. 30, 12 cases, 9 deaths; Progreso, Sept. 20-27, 1 case; Vera Cruz, Sept. 20-26, 49 cases, 17 deaths.
Venezuela: Maracaibo, July 5-11, 1 case, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Aug. 16-22, 29 cases, 22 deaths; provinces, Aug. 16-22, 5,663 cases, 3,811 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Aug. 29-Sept. 5, 8 deaths; Madras, Aug. 22-Sept. 5, 5 deaths.
Straits Settlements: Singapore, Aug. 8-22, 11 deaths.
Turkey: Syria, Birejik, Sept. 24, prevailing.

PLAGUE—INSULAR.

Philippine Islands: Manila, Aug. 16-22, 4 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Aug. 31-Sept. 13, 42 cases, 20 deaths.
Chile: Iquique, Aug. 21-28, 14 cases, 8 deaths.
Egypt: Alexandria, Aug. 29-Sept. 4, 6 cases, 4 deaths.
Japan: Yokohama, Aug. 22-29, 1 case, 1 death.
Mauritius: July 17-Sept. 3, 111 cases, 55 deaths.
Turkey: Smyrna, Sept. 29, 1 death.

Original Articles.

TALMA'S OPERATION IN CIRRHOSIS OF THE LIVER.

M. L. HARRIS, M.D.
CHICAGO.

Since Greenough's recent article[1] contains a list in detail of the cases of ascites due to cirrhosis of the liver operated on up to the end of 1902, no attempt will be made to review the literature. The author desires, however, to briefly mention his own experience in operating on this variety of cases.

In an article on this subject in THE JOURNAL of the American Medical Association, May 3, 1902, the author reviewed the available literature up to that date and published two cases of his own. Since then he has operated on four more cases, making six altogether. The two cases previously reported were:

CASE 1.—Man, aged 56, hard drinker; atrophic liver, enlarged spleen, jaundice, ascites; duration about one year: tapped nine times. Omentum greatly thickened and very vascular. Operation March 30, 1900. Abdomen closed without drainage. Recovery. No improvement. Died in three weeks. Autopsy showed cause of death was cerebral hemorrhage.

CASE 2.—Man, aged 55, hard drinker; atrophic liver, spleen enlarged, ascites; duration about four months. Edema of feet; marked arteriosclerosis. Operation July 10, 1901. Abdomen closed, no drainage, recovery. Tapped three times after operation. Died in two months.

The unpublished cases are:

CASE 1.—F. P., aged 40, farmer. Admitted to hospital Oct. 23, 1902. Family history negative. Had pneumonia at 14 and smallpox at 18. No venereal history. Had taken alcoholics freely for years.

Present trouble began about six years ago with weakness, pain in the right side in region of liver, with slight jaundice. Since then has gradually lost in weight and strength. About six weeks ago noticed that his legs and abdomen began to swell. Has had considerable bleeding from the nose.

Examination.—Poorly nourished; complexion sallow, conjunctivæ icteric; tongue coated. Heart negative; double hydrothorax. Few dry râles at apex of left lung. Abdomen moderately distended with fluid. Edge of liver felt hard and granular. Spleen enlarged. Urine clear; 1003; slightly acid, yellow. Urea 0.5 per cent., no albumin, no sugar, no casts. Was tapped once. Fluid was alkaline, sp. gr. 1009. Did not coagulate. Contained red blood cells, some normal, others crenated and a few leucocytes.

Diagnosis.—Cirrhosis of liver with ascites.

Operation.—Oct. 30, 1902. Median incision above umbilicus. Liver was hard and granular, but apparently not much diminished in size. Parietal peritoneum denuded by scraping with scalpel and omentum stitched to it over as large an area as possible. As the gall bladder was quite large and distended it was drained through a second incision. Incision in midline closed without drainage.

Recovery. After two weeks he was up and around. Some fluid reaccumulated in the abdomen, but not enough to require tapping. He carried a bottle pinned to the dressing, into which the bile drained. He felt quite bright and was very active, while before the operation he had been confined to his bed. On November 26 he took an ordinary dose of Epsom salts. This produced considerable griping. He became collapsed and died in a few hours.

Autopsy.—Limited to abdominal cavity. Considerable fluid in peritoneal cavity. Liver firmly adherent to diaphragm. Omentum, transverse colon and stomach adherent to parietal peritoneum. Liver very small, markedly granular and cuts with greatly increased resistance. Spleen enlarged, firm and of a dark reddish color. Liver with portion of diaphragm, mesentery, etc., removed for microscopic examination. Peritoneum showed marked thickening of the endothelial layer. Hyperplasia of subendothelial connective tissue with slight diffuse round cell infiltration.

CASE 2.—E. W., aged 43, watchman. Family history negative. Excessive smoker of cigars and pipe. Heavy drinker; daily average six glasses of gin, eight of beer and an occasional whisky. Specific infections denied. In 1891 lost right arm in railroad accident.

General health fair until about four years ago, when he was admitted to Alexian Brothers' Hospital with ascites. He remained in the hospital about three weeks and was tapped three times. He left improved, and continued feeling fairly well without reaccumulation of the ascites for about three years. The abdomen then became distended and he was tapped once. Following this was about one year of comparative health. The only complaints were a rather poor appetite at times and an occasional attack of diarrhea, alternating with constipation. Two days ago he caught cold and the abdomen rapidly filled again. He had considerable paroxysmal pain in the abdomen. No vomiting, but eructations of gas.

Examination.—On entering the hospital, Dec. 22, 1902, examination showed a well-developed man, though beginning to show emaciation. Skin and conjunctivæ distinctly icteric. Right arm absent. Slight edema of legs.

Heart: Apex in fourth interspace one inch inside of nipple. Rhythm rapid but regular. Second sound accentuated. No murmurs. Lungs: A few râles.

Abdomen: Filled with fluid; superficial veins distended; a distinct line of dilated capillaries following the costal arch on each side. Upper border of liver at fifth rib in mammary line. Lower border not distinctly outlined on account of the ascites. Spleen not palpable.

Urinalysis: 1020, dark brown. Urea, 2.4 per cent. Alb. +; sugar —; bile +. Microscopic: casts, erythrocytes, leucocytes and epithelial cells.

Blood: Reds, 3,976,000; whites, 2,750; differential count, 400 counted. Polymorphonuclear, 84 per cent. Small lymphocytes, 12 per cent. Large lymphocytes, 4 per cent. One eosinophile.

Jan. 1, 1903, tapped and 3,000 c.c. fluid withdrawn. Fluid alkaline, bile stained. Contained albumin. The fluid was

1. Am. Jour. Med. Sci., 1902, cxxiv, p. 979.

centrifuged and the cells stained. Result: Polymorphonuclear 84 per cent. Lymphocytes, 16 per cent.

Operation.—Jan. 6, 1903. Median incision above umbilicus. On getting through the abdominal wall very extensive adhesions were found attached to the omentum and colon. The veins were greatly enlarged and considerable hemorrhage was encountered. The adhesions were so extensive that it was impossible to get through them into the abdominal cavity. Another incision was therefore made below the umbilicus. This entered the free cavity. Examination now disclosed the most extensive adhesions, involving the entire omentum throughout the length of the transverse colon. The liver was also adherent to the diaphragm. The spleen, stomach, gall bladder and edge of liver could not be palpated at all, owing to the mass of adhesions. The walls of the small intestine were unusually thick and edematous. As there was no hope of making adhesions any more extensive than were already present, the incisions were closed.

Patient died Jan. 12, 1903, six days after the operation.

Autopsy showed typical contracted liver adherent to diaphragm, with extensive adhesion of omentum, etc., to anterior abdominal wall. Collateral circulation was well established and the veins very large.

CASE 3.—Wm. K., aged 36. Bartender. Family history not known. Smokes and chews tobacco to excess. Has tended bar for 20 years. During first ten years drank only a few glasses of beer a day; during last ten years drank from 15 to 18 whiskies a day with the beer, and for the past year drank even more heavily. Has had measles and smallpox, gonorrhea, but no syphilis.

Present Trouble.—About one year ago began to have morning vomiting. A drink of whisky would stop vomiting and nervousness. Occasionally could not retain his meals. Appetite variable. Easily fatigued. Slept poorly. Troubled with alternating constipation and diarrhea. About four months ago he began to have chilly feelings once or twice a week followed by sweats. Five months ago jaundice gradually appeared without pain. Stools for past week have been clay colored and pasty. Three days before entering the hospital pain, cramping in character, appeared in the right hypochondriac region and he noticed that the abdomen began to swell.

Examination.—Entered hospital Feb. 26, 1903. Weight, 120 pounds. Loss in past year, 30 pounds. Skin and sclera deeply jaundiced. Lips dry and cracked. Tongue furred. Showed marked symptoms of cholemia.

Heart: All sounds weak. Lungs: A few râles. Liver dulness extends about 3 cm. below arch. Spleen not palpable.

Abdomen considerably distended with fluid. Hemorrhoidal veins greatly distended and dilated. Knee reflexes absent. Eye reflexes present.

Urinalysis: Color dark, greenish cast, turbid, alkaline 1008. Urea, 0.2 per cent. Albumin trace. No albumose, no sugar. Bile, much. Hyaline and granular casts few. Leucocytes and epithelial cells.

Blood examination: Reds, 3,160,000; whites, 25,600; polymorphonuclear, 75 per cent.; large mononuclear, 13 per cent.; small mononuclear, 12 per cent.; no eosinophiles; hemoglobin, 50 per cent.

Inoculations were made from the blood drawn from a vein in the arm, but no growths were obtained.

Operation.—Longitudinal incision right border of rectus. No adhesions of omentum present. Gall bladder filled, but not abnormally distended. Liver decidedly cirrhotic, very firm in consistency; surface granular. On the inferior surface of the liver about the hilus were two or three lobules or masses about the size of hens' eggs. When first palpated they felt like a malignant growth, but closer investigation showed them to be composed of tissue similar in appearance to the surrounding liver.

The gall bladder was stitched in the upper edge of the wound and drained. A large pocket was formed by dissecting up the inner layer of the sheath of the rectus, and into this the omentum was placed and stitched with catgut. The incision was closed up to the drain. His symptoms of profound cholemia or intoxication continued unabated and he died on the second day. No autopsy permitted.

CASE 4.—Mrs. E. C. S., aged 43. Father and mother living and well, aged 68 and 62 respectively. Six sisters living and in good health. Was healthy as a baby and throughout youth. Had usual diseases of childhood, except scarlet fever. Menstruation began at 13. At 18 was treated for chlorosis. At 27 had diphtheria, was very sick for four weeks, but recovered without complications. Married at 30. Has had two abortions, both induced by drugs at about the third month. Contracted syphilis at about the age of 25. Has been an excessive drinker of coffee, especially for past eight years. Drinks coffee at each meal and often between meals.

About two years ago patient was taken with attack of severe pain in right hypochondriac region. These attacks would recur at irregular intervals and often with increased severity. About one year ago began to have trouble with her stomach. Had feeling of fulness and distress in epigastric region with vomiting and palpitation of the heart.

About nine months ago had attacks of pain in both hypochondriac regions and soon thereafter first noticed abdomen enlarging. In July, 1902, was tapped and a large amount of fluid removed. Since then has been tapped fifteen times and from two to four gallons of fluid removed. At last tapping but little fluid was obtained, although abdomen was greatly distended. Constipation has been the rule. Has never been jaundiced. Is troubled considerably with dyspnea and cough with expectoration of tenacious mucus. Has lost considerable flesh. Legs somewhat edematous. Abdomen greatly distended.

Urinalysis Nov. 25, 1902: Acid, 1020; urea, 1.2 per cent.; albumin, —; sugar, —, casts, —.

Operation.—Nov. 25, 1902. Abdomen opened in the midline above the umbilicus. The most extensive adhesions were found between the omentum and anterior abdominal wall. The liver was adherent to the diaphragm and the gall bladder and edge of the liver could not be located owing to the mass of adhesions. As no more extensive adhesions could be produced the abdomen was closed. No improvement followed. She left the hospital Jan. 6, 1903, and went to a neighboring state, where she was heard from last about five months after the operation. The abdomen filled and tapping was necessary.[2]

Of the six cases, five were dead inside of a month after operation and one was alive, but without improvement, five months after operation. The five cases that died were undoubted cases of alcoholic cirrhosis; the one that was living at the end of five months was in all probability due to syphilis. All of them were far advanced when operation was undertaken, and, while it can not be claimed that any material improvement followed the operation, the cases are of interest and show some instructive points.

In two of the cases, in addition to omentopexy, cholecystostomy was performed in order to drain the gall tracts for the purpose of relieving, if possible, the so-called cholemic symptoms. Death followed in one of the cases in a few days; in the other, some apparent improvement occurred. From a bedridden patient, he was able to be up and about, became quite active mentally and physically, and the color of his skin cleared up considerably. The bile flowed freely. Just as we were feeling encouraged somewhat over his condition, he rather suddenly and quite unexpectedly died. We believe, however, that drainage of the gall tracts in connection with Talma's operation may be desirable in some cases showing cholemic symptoms.

The case of E. W. is of particular interest. A hard drinker, entering the hospital first in 1898 with distinct symptoms of cirrhosis with ascites. He was tapped three times in three weeks. The abdomen did not refill again for about three years, during which time he felt

2. Since writing this I have learned that the patient has died.

fairly well. Why did the ascites remain absent for such a long time following the three tappings? It is well-known that ascites sometimes disappears following the reduction in size of an enlarged and congested liver; but such can scarcely have been the case here, for the condition was one of a markedly contracted liver. It is also known that adhesions occasionally take place after tapping. The most probable explanation, therefore, is that the extensive adhesions which were found at the operation between the omentum, liver and abdominal parietes, and which were evidently of long standing, formed at the time of the first tappings, and the collateral circulation which resulted was sufficient to prevent the reaccumulation of the fluid for some time. If this explanation be correct, the case furnishes an excellent illustration of the benefits which might be expected at times to follow Talma's operation under favorable conditions.

The case also shows, as does that of Mrs. E. C. S., that, notwithstanding the most extensive adhesions, the time comes, sooner or later, when even a free collateral circulation is insufficient to prevent the development of ascites and the progress of the case to a fatal issue.

These cases also tend to confirm the statement of the writer in the article above mentioned on this subject to the effect that the congestion of the portal radicles was not the sole cause of the ascites, but that the changes in the peritoneum of a chronic inflammatory nature were instrumental in its production, particularly during the terminal stage. The fact that the fluid taken from the abdomen was hypertonic in the two cases, as shown by its crenating effect on freshly drawn blood cells from the same patient, is another evidence of the inflammatory character of the fluid.

In conclusion, the writer is of the opinion that the benefits to be derived from Talma's operation in alcoholic cirrhosis, even under favorable conditions, are but temporary. (In 105 cases collected by Greenough, but 9 showed improvement after two years.) In order to obtain the full benefit of the operation, it should be performed early, at the first appearance of ascites or even to anticipate the ascites, if possible. In cases showing jaundice or symptoms of cholemia, cholecystostomy should be performed at the same time.

THE RESTORATION OF THE PERINEUM.*

HENRY O. MARCY, A.M., M.D., LL.D.
BOSTON.

Recent publications show that, notwithstanding the study of the subject by many of our best surgeons during the present generation, there is by no means a general acceptation of any well-settled method for the repair of the injuries of the perineum. On this account I add this contribution, although I have several times published monographs on this subject.

As a primary premise, it may be accepted that the repair of any injured organ should be undertaken to restore it, as far as possible, to its original normal condition. In order to accomplish this, it must be first ascertained just what the normal condition has been. In other words, it must consist of an accurate knowledge of the anatomy and function of the component parts.

The injuries to the perineal structures vary widely. In the minor degree, the hymen, or the vaginal fourchette, may be the only part involved, but such lesion is, of course, excluded, except in the rarest instances, from surgical consideration.

The union of the transversi, interdigitating with the levator ani muscle, making the so-called perineal body, with their connective tissue sheaths, is the more common part to suffer injury. The lesion of these muscles may be central or lateral, a factor of some importance to determine before attempting restoration.

The lack of the central support due to such injury causes the transversi to contract toward their point of origin, resulting in a more or less marked patency of the vulvar opening. Where the injury is within this limit, the sphincter ani muscle, although itself uninjured, is in a measure disabled from the proper performance of its function by being no longer supported anteriorly. On this account the curve of the rectum is lost and the anal aperture falls posteriorly, inducing a saccation or pouching forward of the rectum, resulting in a more or less marked rectocele. *Pari passu,* the cervix is no longer held backward, and varying degrees of uterine displacement follow.

When the lesion has destroyed the entire septum between the vagina and rectum, the laceration is called complete. Of course, the saccation of the rectum does not take place, and more commonly the uterus remains in its normal position.

Since the dissections of Wm. Hunter, undertaken to demonstrate the anatomy and the physiologic function of the reproductive organs during pregnancy, the most valuable contribution to the proper understanding of the anatomy of the pelvic structures in the female are those of Dr. Henry Savage of London. These studies, supplemented by the important teachings derived from the study of frozen sections, greatly modify the previous views of the physiologic relationship of the pelvic organs. The depth of the perineum is less than usually described. The axis of the anus, cutting that of the vagina at nearly right angles, leaves in the external angle an irregular flattened position of tissue rarely, when examined on the living subject, more than one-half an inch in thickness. In the nulliparous woman this is clearly defined as a firm portion of the pelvic floor, and is composed of skin, fat, elastic and connective tissue, transverse muscles, sustaining fascia and the anterior portion of the sphincter ani muscle.

The vaginal side is usually concave and the rectal side convex, owing to the interblending of the sphincter ani. If the finger is carried just within the perineum proper, and a little to one side, there can be felt the firm encircling band of the levator pubococcygeus, attached to each rami of the pubes above and descending to join with the posterior fibers of the sphincter ani and the coccyx. In the perineum, posteriorly, this is firmly interblended on either side with the transverse perineal muscles. These muscles are under the control of volition, in considerable degree, and, acting conjointly, serve to draw the vagina forward toward the pubes.

The parturient and fecal canals are supported in the pelvic basin in close opposition, and the functional relationship is often such that the one may encroach on the other, in a way so as to occupy nearly all the space accorded to both. This is especially true in parturition, when the rectal space is reduced to a thin, folded, flattened tube; and often in elderly women, with old perineal lacerations, the rectum becomes saccated, pushing forward the posterior vaginal wall, forming a considerable-sized external tumor. The pelvic floor is so formed and blended about these openings that it not only sup-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

ports these canals, but also materially aids them in their physiologic function. In intimate relation to both are the bladder and uterus in their ever-varying functional activity, and each is surrounded by a delicate plexus of nerves and vessels.

The sacral prominence throws a large proportion of the abdominal weight on the symphysis pubis and the recti muscles in the support of the body, and thus relieves the pelvic basin and takes off undue strain on the pelvic floor. The rectum is rarely entirely empty, is circular in shape, serves the digestive apparatus, in a measure, as a constantly receiving reservoir, and, when not distended, may be felt from the vagina as a flattened tube curving posteriorly. It is suspended and supported, so to speak hung, by the levator ani muscles which hold the vagina in their encircling loops. On the contrary, the vagina, entirely unlike the earlier diagrams, is flattened anteroposteriorly on itself, and, normally, its walls are, when at rest, ever in close apposition.

The vagina joins with the vulva at right angles to its lateral opening at the entrance of its passage through the pelvic floor.

The vulvar organs are all intimately blended with and go to form a part of the perineum proper. On each side of the vaginal orifice are the erector clitoridis, the bulbocavernosus and the transversus perineii muscles, and these with the levator ani make up, in large measure, the pelvic floor. The bulbi vaginæ and bartolinian glands are covered by these muscles with their erectile plexus of vessels and abundant distribution of lymphatics and nerves.

The erector clitoridis and bulbocavernosus muscles, with the transversus perineii, join on each side to constitute the ovate muscular vaginal orifice, and in their conjointed action perform a very important physiologic function in sexual congress, often underestimated or ignored. Their impaired function frequently underlies certain reflexive nervous conditions, distinctly pathologic, which are easily overlooked, but are the causes of much suffering and unhappiness.

The much-discussed, so-called perineal body has, in my opinion, misled some of our prominent authors into false positions, and caused great confusion and misunderstanding among physicians.

I have been criticised in emphasizing the muscular floor of the pelvis, and that I underestimate the importance of the variously distributed connective tissue fascia. This is not by any means my intention. The superficial perineal fascia, in its deep layer in the male, as well as in the female, covers and encloses the transversus perinei muscles, forming strong ligamentous transverse bands, uniting in the perineum, designated by Savage as ischio-perineal ligaments. The pubococcygei, acting in unison with the other muscles of the pelvic floor, draw forward and thus aid, not only in closing the rectum, but in holding both it and the vagina in the anterior curve, so important to be retained for the preservation of normal function.

A horizontal section made through the floor, just above the sphincter vaginæ, and posterior to the junction of the transversus perinei, shows the deeper fibers of the pubococcygeus, united in a loop behind the lower border of the rectum, holding it from its fixed point at the pubes, as in a sling. This loop is connected with the transversus perinei, bulbocavernosus, erector clitoridis, sphincter vaginæ and sphincter ani muscles by strong layers of connective tissue, the importance of which, for union and support, can not be readily overestimated.

On the posterior wall of the vagina, in its lower third, longitudinal muscular fibers are found external to the circular layer, and these intimately blend with the pubococcygeus, giving a firm support to the vaginal outlet, quite as the outer longitudinal fibers of the rectum unite with the deep layers of the sphincter ani. The physiologic action of the muscles, thus grouped, serve to draw the rectum forward toward the pubic arch, and this explains, in large degree, why the circular fibers of the vagina, left free to act in other directions, are intrafolded laterally, making in cross section an imperfect letter H, first pointed out by Freund in 1883. The intrafolding of the vagina at right angles to the vulvar outlet is very important in its relationship of support to the uterus and its appendages.

The surgical procedures which have been devised for the restoration of these structures are manifold, and many of them are in the highest degree ingenious, but too often confusing and unsatisfactory.

The study of their history is instructive and profitable, but the field is to me more tempting for review than it is to the junior practitioner, since these various procedures have been elaborated, for the most part, within the period of my surgical experience. I purpose, however, to limit myself to those only which have a bearing on the methods which I have especially commended.

My earlier masters, Marion Sims and Thomas A. Emmet, most ingeniously devised scissors with various curves and dextrously used them to denude the posterior V-shaped portion of the vagina which was thought advisable for coaptation. So exceedingly dextrous were these men that I have seen them pare back and forth a narrow ribbon from this portion of the vagina, leaving the dainty piece unbroken.

My late friend, Dr. Edward Jenks of Detroit, separated this portion of the posterior wall of the vagina as a flap instead of denuding with the scissors and then cut it away and sutured as Sims and Emmet had done. Not long prior to this I had begun the use of buried animal sutures in a considerable variety of wounds, and it occurred to me that, by adopting the method of Dr. Jenks, I could preserve the flap thus separated and coapt the deep structures by sutures buried beneath it.

I soon found that the line of division was not the mucous membrane from the vagina, as these authors had supposed, but the attenuated posterior vaginal muscle, often so thinned out as to be hardly recognizable. For obvious reasons the posterior vaginal fascia holds the vagina loosely to the subjacent structures and the separation is not difficult except when united by bands of cicatricial repair. By this division, it is not difficult to differentiate the levator loop and bring it with the ends of the separated transversi into easy inspection. A further dissection externally on either side of the sphincter ani makes the wound of sufficient size for easy manipulation. This permits the reconstruction of the perineal structures in a simple and easy manner.

With various unimportant modifications, this is the method which I have practiced and taught for more than a quarter of a century.

Finding that the catgut sutures did not always hold the parts in coaptation sufficiently long, I devised a lateral support by means of two or more disjointed pins, which united after their introduction, held the parts in juxtaposition after the manner of an ordinary safety pin. I had the good fortune to obtain tendon sutures

from the tail of the kangaroo which proved reliable and rendered the use of fixation supports unnecessary. Since this period I have used only chromicized tendon sutures with entire satisfaction. These have been, and may be, applied in a variety of manners.

The first step in the operation is to dilate the sphincter. The index and middle fingers of the left hand are introduced into the rectum and retained there until the end of the operation.

The septum is made tense by the retained fingers and a button-hole incision is made on the median line by either knife or scissors. I prefer a double-edged, pointed knife.

Through this opening I introduce a knife of special design. I am sure additions to our armamentarium should not be made without good reason, but this instrument adds materially to both ease and safety of dissection. The cutting part is something the size and shape of the little finger nail and is placed at an angle with the handle, so that when pushed in a direct line the edge is at an angle of about forty-five degrees to the part to be divided. The parts are made tense by the fingers in the rectum and the knife is guided so that neither rectum nor vagina is injured. The lateral dimpled depressions in the vagina mark the site of the separated retracted transversi. Even with a sharp knife these are divided with some difficulty. Elsewhere the separation is easy and is often made almost entirely with the fingers, dividing an occasional cicatricial band by scissors. The Emmet scissors serve admirably for the separation of the vagina from the vulva. The little lateral fold of mucous membrane on either side shows the inception of the original lesion. To these points the dissection is carried anteriorly. Thus the posterior third or more of the vagina is separated from its attachments quite to the crest of the rectocele.

This flap is held anteriorly by an assistant. A large curved needle, firmly set in a handle, with the eye near the point, carries the suture. The fingers in the rectum materially aid in guiding the needle. It is carried through the left side penetrating the transversus and levator unthreaded and withdrawn. Rethreaded, the needle is made to penetrate just above the vaginal junction with the rectum and then is carried through the right transversus, unthreaded and withdrawn. This makes the upper border of the upper stitch. The suture is centered at this point of fixation and held by an assistant. The suture is again carried by the needle parallel to the first introduction—about one-third of an inch below it; unthreaded, rethreaded with the opposite end and withdrawn. This makes a double stitch exactly like that of the cobbler, the needle serving as carrier of the suture from opposite sides. In this way three stitches are usually taken. When drawn on moderately tight, the widely separated structures are evenly coapted on the median line and are held in fixation.

The remaining tissues are united by a light, continuous running suture, best effected by a rather large-sized, full-curved Hagedorn needle. The distal end is fixed by a loop knot and the needle, carried deeply from side to side, places the suture at right angles to the long axis of the wound. Where drawn on, the tissues are evenly coapted in the median line, with no suture material in the line of union save where it crosses at a right angle to it.

I have called this stitch the parallel suture, since the needle is inserted parallel to the long axis of the wound. In this way the entire wound is easily and rapidly closed, the reconstruction being made so complete that the vulvar opening is entirely restored, even to the reformation of the hymen if desired.

When the laceration has been so extensive as to include the sphincter ani muscle and a portion of the rectum we have quite another problem.

The posterior vaginal wall is not thinned out as in rectocele. Quite the contrary, the vaginal muscle is contracted, often the vagina thick-walled. The rectum and vagina are separated quite as freely as in the incomplete form of the injury. This permits the reconstruction of both rectum and vagina by separately reuniting them with continuous sutures, care being taken not to penetrate the bowel or vagina by inserting the stitches from side to side from the dissected surfaces only. The rectal suture must penetrate the connective tissue of the bowel, here much thicker than in the free portion of the large intestine. The vaginal suture is given to an assistant and held forward. The rectal suture is held by the weight of a pair of forceps. The wound is now restored to conditions not unlike those of the incomplete rupture when ready to introduce the parallel double fixation sutures for the reunion of the transversi, and the operation is completed, as above described, only the separated retracted fibers of the sphincter ani muscle must be freed and sutured. The short wound in the median line is closed by a light-running buried suture, the wound dried and sealed with iodoform collodion.

IN RESUME.

By free dissection and the use of buried absorbable sutures, the parts are entirely restored to their former normal anatomic condition and physiologic function. Aseptically maintained, the repair is rapid and painless.

The urine should be drawn for the first days. The bowel is never allowed to become distended with hard fecal masses. In complete laceration, a large rectal tube of soft pure rubber should be used.

RESULTS.

I have within a few days seen a lady on whom I operated thirty years ago by the methods as above outlined. I since have operated several hundred times.

Recently a visiting surgeon, seeing the operation, asked our matron: "How large a percentage of Dr. Marcy's cases have failed of good results?" She looked surprised, but replied: "I do not know of a single case." "How long have you been in charge of the hospital?" "Over sixteen years." So seeming an unimportant operation has it become with us that a careful statistical table could be made only by an amount of research work not deemed necessary, but I am sure the reply of our matron is essentially correct.

DISCUSSION.

Dr. A. H. Goelet, New York—I doubt whether the deep through-and-through suture would succeed in the hands of all who should attempt this operation. The objection is that it constricts the parts, cuts off the circulation and nutrition and often results in failure. I have tried every operation on the perineum, except the Tait flap-splitting operation, which I do not approve, and have abandoned them all for the Hegar-Martin operation in which the denuded surfaces are united by means of buried layer sutures of chromicized catgut. That has given me far better results than any other operation on the perineum and I now never have a failure. It seems to me a valuable point to avoid as much as possible handling the denuded area, and instead of sponging to keep a continuous stream of normal salt solution playing on the wound to keep the field clean. This will aid materially in securing primary wound healing.

DR. F. A. DUNSMOOR, Minneapolis, Minn.—One of the essential things brought out in the paper is that the reason for so many failures in repair of the perineum is that the sutures are not introduced properly; not that they fail to close up the denudation, but the result is not what we should wish it to be. If we are to get any real benefit from this operation in the vagina we must increase the depth of the vagina from the vulva to the region of the cervix, and narrow it from side to side, thus tightening up the relaxed walls. This can be done whether the freshening is made by the flap-splitting method or by any other plan, but it is extremely important that the sutures are passed horizontally and are not to be introduced from the margin of the vulva, then carried to an apex near the emergence of the cervix, returning by a corresponding oblique line to a point opposite that starting. In the latter case, when we tighten the sutures, we bring the upper part of the vagina down toward the lower, and the vagina is widened and shortened. As time goes on the posterior wall relaxes more and more, forming a rectocele. There is a way of overcoming the objection made by Dr. Goelet. If we introduce the sutures in two layers, beginning one-third of an inch inside the margin of the denuded wall on the right side and depress the middle of the denuded septum, emerge for half an inch, and then pick up the opposite side, to within one-third of an inch of left margin, repeating every one-third inch, we will make all the way down a backbone or thick septum. Then while passing the second layer of sutures, pass the needle in the first instance horizontally across to accurately adjust the wound margin. Next through the new body made by the first tier of sutures and include fascia and supporting muscles of each side. Alternate these two styles of sutures until the vulva is reached. The circulation is not cut off. Further, we get a more lengthened perineal body then by any other method, and a support for the rectum, thus correcting the rectocele and assisting the expulsion of fecal matter from the rectum; narrowing the vagina from side to side and increasing its depth. This operation on the perineum should have for its object the restoration of the normal supports of the perineal body and holding it up in a definite position. Dr. Marcy's method of reuniting the divided muscles by suturing at right angles to axis of vagina accomplishes the desired result.

DR. A. M. HAYDEN, Evansville, Ind.—I have made it a point to absolutely coaptate the parts without any wrinkling. I denude and take out the flaps as much as I want so as not to narrow the caliber of the vagina, and then use interrupted or continued catgut sutures, commencing at the lower border and putting them in back and forth. After I get the muscle all coapted nicely, I suture the vaginal mucous membrane from the upper part down to the skin without catching the muscle at all. The skin of the perineum I suture in the same way with superficial sutures. I use two or three layers of sutures to coaptate all the parts and bring them together nicely.

DR. HANNAH GRAHAM, Indianapolis—I have used a method of repairing the perineum for the last four years, but have not published it. I insert a Kelley tenaculum on each side and with the scissors cut straight across. I slip the finger into the rectum and with an ordinary scalpel I make a sort of bib-shaped denudation. Instead of cutting down and making a Y-shaped denudation, I denude perfectly straight. Then I pull down the center point of the upper edge of the denuded area to about the site of the fossa navicularis, where I unite it on each side with a continuous catgut suture, after having united the edges of the transversus perinei with a buried suture. I have used this method in cases of prolapsed uterus and it has held the uterus up very well. The perineum does not stretch out as I have seen it do with other methods, and I have examined patients who have had as strong a perineum after four years' standing as immediately after the work.

DR. R. H. GIBBONS, Scranton, Pa.—If Dr. Marcy's stitch is properly introduced and fixed it can not cause choking of the muscular structures or vessels; nothing but good can happen. I tried it on many occasions and it was the fault of the absorbable material that I gave it up and also because I went back to my first love, Dr. Emmet's method. I can do this operation better than any other and I believe it meets every indication. Those who talk of the operation of exposing the muscle where it is torn, Reed, Harris and others, claim that Emmet's operation will not do what he claims for it. If the denudation is properly made all the separated fibers of the muscle are exposed, and if the stitches are properly applied all the parts must be brought into apposition. If you pass the suture downward from the very apex of the denudation and bring it down into the muscle, you catch the principal fibers of the muscle, and passing it down, the lower fibers are caught, thus bringing all the fibers in apposition. There is no operation that can improve on the Emmet method if it is learned from Emmet or his students. Dr. Marcy's operation is the first of what are termed modern operations and he is entitled to credit for having formulated a method of introducing a buried absorbable suture that fixes the parts and keeps them fixed without strangulation. Dr. Graham has introduced a very practical point, the idea that the first stitch usually throws the apex of the rectocele high up where it should be after the method of Andrews of Chicago.

DR. A. H. GOELET, New York—I overlooked a point in my previous remarks which is very important in obtaining primary wound healing, and that is to keep the wound dry. Many practitioners who are compelled to do this operation are obliged to practice without the aid of a nurse and who must care for the patient after the operation, can avoid the necessity of coming back a number of times a day to catheterize. I have had made a rubber perineal shield which has a little tongue that is inserted into the vagina and catches under the urethra forming a gutter for the urine. It is strapped with adhesive plaster to the thighs, so that when the patient urinates the urine passes down the gutter into a bedpan beneath without soiling the perineum. The perineal wound can then be dressed with gauze beneath this shield and can be kept dry just as any other wound. This shield is not, of course, necessary when the services of a skilled nurse is obtainable, but it adds greatly to the comfort of the patient if repeated introduction of the catheter can be avoided, and I regard it important to prevent contamination of the wound by the urine.

DR. WALTER B. DORSETT, St. Louis—I object to the word denudation. It implies very little. Usually when we speak of denudation we mean that we take off the mucous membrane. If we are going to make a perineum that is going to be of any service, whether for rectocele or simply for a relaxed outlet, we have in the first place a stretching of the mucous membrane, together with a stretching of the vagina, a stretching of the circular muscle fibers of the vagina; therefore, in order to repair that properly we must do something more than a simple denudation; we must take out sections from the vagina. I commence on one side and cut deeply until I get beneath the vagina, then I take hold of it with a pair of forceps, pass my fingers up and dissect the vagina from the rectum. Then I begin at the upper angle and introduce the sutures. (Dr. Dorsett illustrated his technic.) When I draw on the upper suture I lift up the whole perineal body. If we simply denude, as I have seen many surgeons do, we fold the connective tissue together, and if we get any union at all it is only by slight adhesions, and it is of absolutely no benefit. The operation I do is essentially that given us by Emmet.

DR. J. H. CARSTENS, Detroit—Concerning the denuded surface, what is there in the first place? A ruptured perineum, torn fascia everywhere and a muscle that is torn completely through. If there is an Emmet suture put in, I do not care which way it is pulled, on being drawn together it puckers up. One can not do anything different with a large suture. One can not get the parts accurately together. (Dr. Carstens then illustrated his method on the blackboard.) I put in thirty or forty stitches and build up a perineum that is as near like the original perineum as I can make it. Ideal surgery is to use the buried suture, and not the big *en masse* suture, which is a catch-as-catch-can suture. If you hit it, all right; if not, then you don't.

DR. A. PALMER DUDLEY, New York—What is the pelvic floor? The levator ani muscle; the transverse perineal muscle from the ramus around to coccyx and to anus. What is split? The perineum. What is the perineum? The two halves of the

levator ani muscle. You get them together to have a returned sphincter action. I am going to reverse the order of operation on the perineum entirely. The muscle is surrounding the vagina; it is ruptured. If you make Emmet's operation where is the fixed point, and from where are you drawing tissue? You are drawing movable vaginal tissue. If you will do a proper operation you must denude and use some suture which will unite the muscle end to end and not to cellular tissue or mucous tissue. (Dr. Dudley demonstrated his points on the blackboard.)

Dr. H. O. Marcy—The premises I took at the opening are verified. There is as yet an entirely unsettled idea as to what we should do in restoration of the perineum. Two or three things should be settled on here and now, and the discussion aids in elucidating this matter. I omitted much in the reading of my paper in order to save time. The whole idea is that we must reunite the ruptured muscles in the median line, where the interdigitation of the transversi with the levatores make the so-called perineal body. How this can best be effected is the problem. That which I claim to be of advantage is, that in dissecting up the posterior two-thirds of the vagina we are enabled to reach and reunite the separated structures. Into the vulvar opening, thus restored, we suture the thinned-out vaginal muscle sheath, much as the tailor the sleeve into the arm hole of a coat. In this reconstruction, all the tissues are utilized. Nothing is dissected away. The process of restoring the soft parts is simple and easy. The operation is really done in half the time I am discussing it. Dr. Goelet's criticism is well taken if too much force is applied in the constriction of the sutures. Retention at rest of the reconstructed tissues without constriction is of vital importance in the application of all buried sutures. Continuous suturing is safer than interrupted stitches, since the force must act equally on every stitch. The wound must be protected from the urine. With the assistance of trained nurses I have operated on several hundred cases without a single failure.

THE REPAIR OF CYSTOCELE

BY UTILIZATION OF THE ANATOMICALLY FIXED POINTS IN THE ANTERIOR VAGINAL WALL.*

E. REYNOLDS, M.D.
BOSTON.

A year ago I read before the American Gynecological Association a paper on this same subject, setting forth what I believed to be somewhat new and important points in the repair of cystocele. My object in this present paper is to restate the facts and conclusions then brought forward, with the developments which have been obtained in another year of work, and supported by the ultimate results of the cases then reported.

We hear nothing nowadays of new methods of operation in the repair of the lacerated cervix, and for several years have heard nothing of new methods in the repair of the perineum. These operations are satisfactory. The anatomic principles on which they were founded are well worked out, and there is little more to say about them, hence the silence. The third great plastic—the operation for the repair of cystocele—stands on very different ground. New operations are still proposed almost as frequently as in the early days of plastic operating, and we should most of us agree at once that no one of all these many operations and no group of operations has overcome the others and become accepted. I believe that this uncertainty and unsatisfactory state of the cystocele operation has been due to our failure to comprehend until recently the anatomic conditions, an observance of which must necessarily underlie all successful repair, i. e., I believe we have been in the habit of puckering up the loose tissues by merely empirical methods, and have not searched intelligently for the anatomic supports of the wall and sutured them directly to each other. If the operation is ever to be put on a rational basis, the first step in the process must be an inquiry into the anatomy of the anterior vaginal wall; and to state the results of such an inquiry is the first purpose of this paper.

The structure usually spoken of as the anterior vaginal wall is really two structures and is composed of the loose, elastic, non-resistant posterior wall of the bladder in combination with the strong sheet of muscular and connective tissue which forms the true anterior vaginal wall, but which may be here called for distinction the vaginal plate of the anterior wall. The vaginal plate is but loosely attached to the bladder, is normally firm, non-distensible, and strongly fastened to supporting tissues on all sides. It is attached at its lower end to the tissues immediately behind the pubic bone. At its upper end it is inserted by its central portion into the cervix and, which is of more moment, by its lateral corners into the important masses of connective tissue and unstriped muscular fiber which extend through the lower portions of the broad and uterosacral ligaments to find their attachments in this vaginal plate and in the supravaginal cervix. By its lateral edges throughout it is attached to the pubococcygeal and the allied group of transverse muscles which here find their only insertion into the vagina. To recapitulate: In the normal state these strong supporting structures are inserted into the four edges of the strong sheet of muscular and connective tissue which we know as the anterior vaginal wall, and are by it bound together into a firm floor which supports the bladder, the whole being in its turn reinforced, but only reinforced, by the support of the posterior vaginal wall below it.

This being the normal anatomy of the anterior vaginal wall, we should next inquire into the anatomic conditions which prevail in cystocele, and this is perhaps best reached by considering the conditions which are found during and at the close of labor.

It must be remembered that the posterior vaginal wall is mainly, and the anterior wall is wholly, supported by structures springing from the anterior half of the pelvic bones, hence it happens that while the walls themselves are exposed during labor to almost equal distending forces, the supports of the anterior wall are subjected to but little strain, and may even be relaxed by its forward distension during labor, while the supports of the posterior wall are subjected to great strain during its backward and downward distension, and in the concluding stage of labor the posterior wall and its attachments receive almost the whole strain of the advancing head.

The result is that the distended posterior wall is exposed to laceration, while the anterior wall, though always distended, is seldom lacerated. At the conclusion of labor, then, the attachments of the anterior wall are intact, but the wall itself between the attachments is greatly distended and therefore sags forward and downward under the influence of gravity. The natural result is that when the support of the posterior wall has been lost the vaginal plate often fails to recontract during involution, loses resiliency, and no longer supports the bladder, though its edges are still inserted into the intact supporting structures. This is, then, the anatomy of cystocele, and the condition is, in effect, a hernia of the bladder through the foramen formed by the attachments of the anterior vaginal wall, carrying before it as its

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

distended and overstretched covering the vaginal plate of the anterior vaginal wall. A persistence of this condition is, in my mind, the anatomy of cystocele, but whether this theory of its causation be right or not, it is a fact, as anyone may convince himself by examining a series of cystoceles, that the central portion of the vaginal wall has lost its elasticity and becomes thinned and non-resilient; the weakening process being most marked at its center, and decreasing until at the upper and lower extremities and also at the lateral edges, the wall is still thick, strong, and held firmly in place. It is, then, this hernial condition which we are to repair.

It is an universally conceded principle in other hernias that an operation which pushes back the distended sac and unites its surfaces to each other will be inferior to an operation which excises the sac and brings together the actual raw edges of the supporting tissues which surround it. I believe that we shall find that the essential weakness in the many operations proposed for cystocele lies in our habit of merely refreshing the vaginal surface by superficial denudations and so uniting only the already overstretched and comparatively useless tissues of the hernial sac, instead of searching, as in other hernias, for the insertions of the supporting muscular attachments and uniting them directly to each other after an excision of the overstretched tissues. I believe that if this is done the actual shape of the excision is carried into the unthinned portions of the wall, and that the direction of the sutures is such as to bring the supporting structures together. The actual excision of a large portion of the anterior vaginal wall sounds at first like a far more severe affair than a denudation, but even if that were so, we have learned not to be afraid of severe operations for adequate cause, and, as a matter of fact, its technic is so exceedingly easy, simple and rapid that I do not think that any man who has even once performed the operation will look on it as being, in fact, more severe.

One further piece of anatomy should, however, be here referred to, since it is frequently of essential importance to a good repair, viz., the anatomic conditions present when cystocele is complicated by descent of the cervix. Even when this complication is present the conditions insisted on above will be found but little altered. The lateral and lower attachments of the vaginal plate will be found non-stretched, and even its upper lateral corners are, in point of fact, but little displaced, i. e., their supports are but slightly stretched and require for the replacement of the upper end of the vaginal wall no more than a slight shortening of their ends, but it is here essential to good repair that the cervix should be extensively freed from the central portion of the upper end of the anterior plate and from the bladder as well, both to prevent further tendency toward displacement, and also to permit the cervix to move backward and upward into its original position before the sutures are brought together. The condition is still a hernia of the bladder, though complicated by slight overstretching of the supports of the upper lateral corners, and by a traction on the cervix which must be released as one essential step in the operation.

While this paper was in process of preparation I was much interested in reading an article by Hirst of Philadelphia in which the importance of bringing together the intact lateral supports is detailed, although the necessity for excising the weakened portion of the vaginal plate is not recognized. I was still more gratified by a paper[1] by Dudley of Chicago in which my former paper is referred to most kindly. In it the principles then enunciated are adopted as the necessary foundations for the repair of cystocele, the necessity for so shaping the excision as to throw the cervix well backward is described more forcibly than I had heretofore succeeded in doing, and an operation of Dr. Dudley's own devising is described. I can not help thinking that the shapes of both Hirst's and Dudley's operations are a little unnecessarily complicated. I believe that any operation which is to be successful must be so shaped and the stitches so inserted that both the lateral and upper and lower supports of the anterior vaginal wall will be utilized, i. e., so planned that the broad ligament attachments of the upper lateral corners and the firmly supported lower end of the wall will be brought together, as well as the insertions of the transverse muscles into its lateral edges. I think that if Watkin's operation or Emmet's latest operation were made excisions instead of denudations they would often fulfill well the anatomic conditions. I think that the operation which I have to report, as having been successful in my own hands, is, so far as the shape of the excised portion of the wall is concerned, merely one of many which might be devised, and probably one of many modifications which should be used for the differing forms of cystocele.

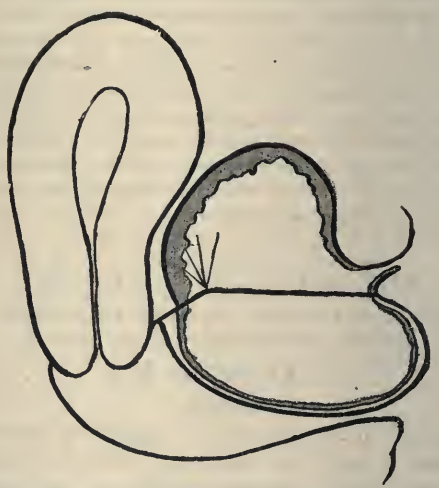

Fig. 1.—The heavy straight line shows diagrammatically the line of the repaired anterior wall.

In short, I do not think that any of us have as yet evolved an operation which is perfect in its details, but, although I have been trying during the past year several modifications in the shape of the excised areas and the insertion of sutures, I have so far found none which has yielded me as good results as the operation which I reported last year, and have now to describe again.

Its main features of value are that it throws the cervix far backward into its original position and that while it shortens the vagina enough to restore the upper and lower supports to their original position, it is essentially a transverse operation.

The anterior wall having been exposed, preferably in Sim's position, the points AA (Fig. 2) at the sides of the cervix are marked by tenacula or tissue forceps. The point C, the highest point in the anterior wall which is still entirely intact and unthinned, is seized with tissue forceps and pushed upward along the median line until it is on the stretch. The points BB, situated laterally exterior to AA, are then selected as those which can be drawn by tenacula or tissue forceps into apposition with

1. THE JOURNAL A. M. A., April 4, 1903, vol. xl., No. 14.

C on the median line, and are similarly marked. The crescentic area indicated in the diagram is then lightly marked out with a knife as a guide in the excision of

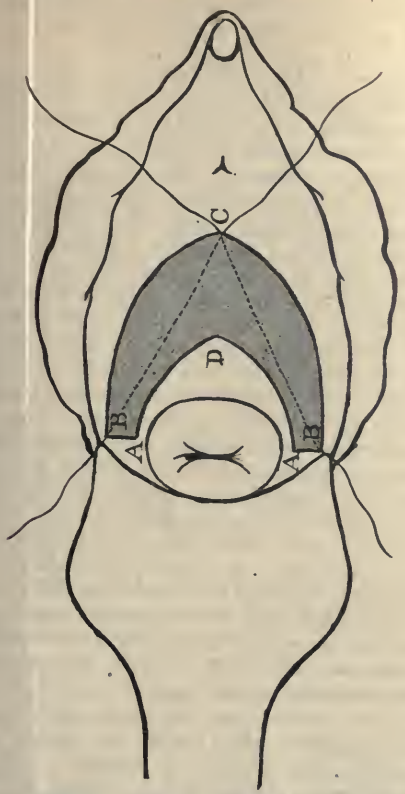

Fig. 2.—The excision complete and the primary sutures inserted.

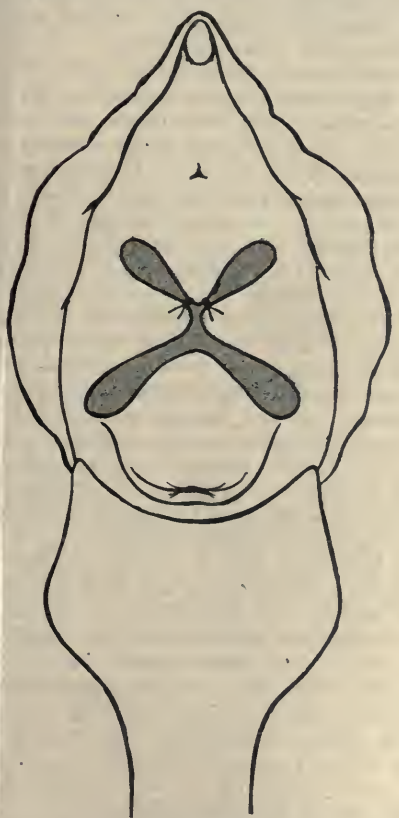

Fig. 3.—The first suture tied and the cervix thrown strongly backward.

the weakened portion of the wall, the point D being not more than half an inch in front of the cervix. Its exact position is unimportant. A short transverse incision at C is then carried through the vaginal wall until the point of cleavage between this wall and the bladder is found. The handle of the scalpel is then pushed upward, easily separating the vaginal and bladder walls until it is seen to reach the inner edge of the crescent at D.

The vaginal wall is then, as a matter of convenience, divided along the dotted line CD, and the vaginal and bladder walls are then rapidly and easily separated by the handle of the scalpel over the whole of one lateral half of the area marked out by the knife. The separated vaginal wall is then removed with the scissors and the process is repeated on the opposite side, leaving the uninjured bladder wall exposed over the whole crescentic area. The bladder is then separated from the supravaginal cervix and muscular fibers of the broad ligaments to the level of the internal os, a point the importance of which can hardly be overestimated, more

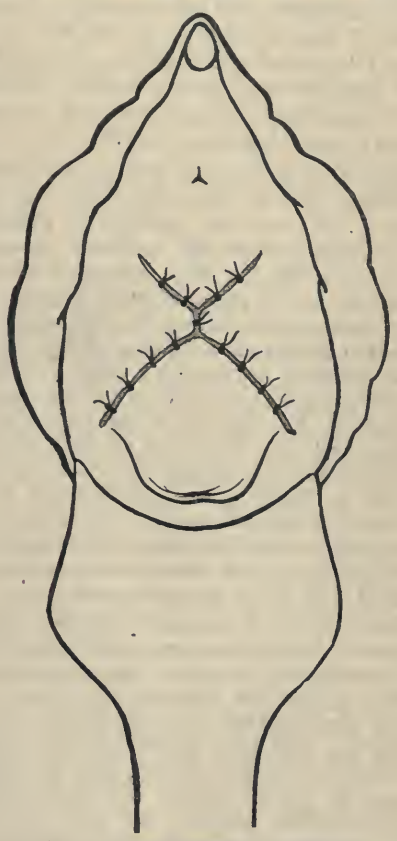

Fig. 4.—The operation completed.

especially in the presence of descent of the cervix. The points BB are next connected with C by sutures as indicated in the diagram, at C the needle being made to pass deeply through the whole thickness of the vaginal wall, and at B still more deeply in order to catch the fibers of the lower portion of the broad ligament; these sutures having been tied, the incision falls into the shape shown in the third diagram; the remainder of the wound is rapidly whipped together with a running catgut suture, the needle passing at each insertion through the whole thickness of the vaginal wall, and the operation is thus completed, the lines of union lying in the form shown in the fourth diagram.

As the result of this operation, the cervix is thrown markedly backward and the anterior vaginal wall is therefore in appearance rather lengthened than shortened, but its attachment has been transferred to the firmest supports of the vaginal vault, the bases of the

broad ligaments; the uterus has thereby been relieved of weight, and is found to be higher rather than lower; and the wall, as a whole, is drawn upward and forward behind the pubes in a way which affords a surprisingly firm support for the base of the bladder. (See straight lines on Fig. 1.) It might appear at first sight that a cavity would be left between the unaltered bladder wall and the line of union of the vaginal wall, but in practice the contractile bladder wall at once shortens itself to its new position, and no such cavity is left. The only vessels divided are situated in the vaginal wall, and bleeding is consequently controlled by the sutures. In practice I have had no trouble from this source. The only objections to the operation which I have been able to find so far are that in case of failure of union a secondary operation would be more difficult than after a simple denudation, and that it is not well adapted for performance at the same sitting with the repair of an unusually deep laceration of the cervix. An ordinary trachelorrhaphy does not interfere with it.

Last year I reported immediate good results in five cases, the ultimate results of which I have now looked up. I have since performed it with uniform satisfaction in many more recent cases.

CASE 1.—Mrs. A. D. P., aged 38, is the mother of three children, the youngest aged 3. The heart, lungs and urine were normal. Uterus was heavy and retroverted. There was moderate cystocele with considerable rectocele. Operation was performed Jan. 24, 1902, in the presence of Drs. Hubbard, Wadsworth and Allen. The cystocele was treated by the method described. Perineorrhaphy and ventrosuspension were done with exceptionally good results. To-day, fifteen months after operation, the perineum has yielded a little, but the anterior wall is nevertheless as firm as at the end of the operation.

CASE 2.—Mrs. M. Mc., aged 52, is the mother of two children, youngest aged 20. The heart, lungs and urine were negative. There was cystocele and rectocele. Operation was performed Jan. 30, 1902, in the Free Hospital for Women. Cystocele treated by method described. Perineorrhaphy was done and the perineal result was good. Operation on cystocele was exceptionally good. Has moved and been lost sight of; when last heard from result was unchanged.

CASE 3.—Mrs. N. M. B., aged 56, has ten children, the youngest aged 21. She presented no constitutional symptoms. There was cystocele with rectocele. Operation was performed March 4, 1902, in the Free Hospital for Women. Cystocele operated on by above method. Perineorrhaphy was done; the results were good. Seen April 30, 1903; result admirable.

CASE 4.—Mrs. A. D. W., aged 65, has five children, the youngest aged 30. Heart, lungs and urine were normal. Fundus was in normal position, but there was a greatly elongated and supravaginal cervix with prolapse of the anterior and posterior vaginal walls. Operation was performed March 18, 1902, in the Free Hospital for Women. The cervix was amputated. Cystocele operated on by above method. Perineorrhaphy was done. The result is good. Uterus outside of vulva. This was a large, stout, aged woman who has been doing hard work, whose perineum has yielded utterly as well as the cystocele. It is probable that no plastics would have been enough and that an abdominal operation should have been performed in addition. The typical cystocele operation was further complicated in this case by amputation of the cervix and consequent impairment of the whole vaginal vault.

CASE 5.—Mrs. E. K., aged 49, is the mother of two children, the youngest aged 26. She entered the Free Hospital for Women with pain about an encysted hydrocele of the cord. The heart, lungs and urine were normal. The uterus was retroverted and prolapsed with cystocele and rectocele. Operation was done March 13, 1902. Closure of inguinal ring and ventrosuspension were done by Coley's method. On March 25 cystocele was treated by above method. Perineorrhaphy was done and there were good results all around. She has grown enormously stout since the operation, but when seen, April 30, 1903, had an absolutely good result.

In all these five cases the anterior vaginal wall arched upward and forward in front of the cervix at the end of a year just as it had done immediately after operation.

DISCUSSION.

DR. C. O. THIENHAUS, Milwaukee, Wis.—The methods of operation for cystocele differ according to the malformations present in the individual case and the forms of the cystocele. Take, for instance, a woman of 50, with a prolapse of the uterus together with cystocele, when the vaginal mucosa is thinned by overdistention, for such cases the operation advised by the author to-day is certainly not sufficient. These cases must be treated as a hernia, and last year I advocated the use of the muscular wall of the uterus as a protection against the pressure of the abdominal contents and the bladder. Free the bladder from the elongated cervix and push it up so that it disappears like a ball behind the symphysis and then fix the entire anterior wall of the uterus to the vagina, thereby supporting the bladder by the uterus. This will prevent the descent of both the bladder and uterus. Some have even found this not sufficient, but they fix the posterior wall of the uterus to the vaginal wall, thereby leaving the uterus in the vagina. Reynolds' method is a good one for certain cases, but in every case where there is retroversion of the uterus and the uterus lies in the axis of the vagina, what will happen? The uterus descends more and more with or without elongation of the cervix and the external os soon appears in the vulva. At the same time the bladder is naturally drawn down. Therefore, to correct this condition we must do something for the correction of the causative agent, that is the retroversion of the uterus, and for these cases in younger patients I have advocated, after freeing the bladder and pushing it up as above cited, the vaginal suspension which leaves the uterus in the small pelvis where it belongs, and does not drag it up into the abdominal cavity and against the abdominal wall (as an abdominal suspension), where it does not belong and has no place under normal conditions.

DR. J. WESLEY BOVÉE, Washington, D. C.—The treatment given by Dr. Reynolds is practically correct. We should treat this hernia as we do every other hernia, but we have conditions here which we do not have in the ordinary hernia. He said the operation draws the cervix back, but my impression has always been that any traction on the broad ligament anteriorly tends to drag the cervix forward. I think that the raising of the bladder and the high suturing in front is one of the strong elements which tends to prevent the cervix from taking an anterior position. I practice the method of separating the bladder, raising it and suturing the fascia laterally. I aim to do what I think he fails to do, to push the cervix back. My belief is that it is a better method to put all the sutures transversely and none of them anteroposteriorly. W. H. Byford taught us that the cervix must not be brought within less than 2¼ inches of the posterior surface of the symphysis. And I know that men who are less skilful than Dr. Reynolds in doing this plastic work will occasionally pull the cervix forward by improper traction in that direction if the sutures are placed in the broad ligament.

DR. E. REYNOLDS—I wish to express my interest in Dr. Bovée's criticism and to express my opinion that very much to my own surprise the effect which is produced by these sutures is a transverse narrowing and an elongation rather than a shortening of the anterior vaginal wall. I think I know why this is, but could not give an explanation briefly enough to be proper here. However, I do not care what shape of denudation you make, nor how many sutures you put in, nor how, if you will only get rid of the hernia after a rational method by complete excision of the hernial sac and direct suture of the ends of the undistended tissues.

Flies.—In all diseases in which infection occurs through the alimentary tract, flies should be considered as important carriers of the infection, until this possibility is absolutely disproved.—*Brooklyn Med. Jour.*

REPAIR OF LACERATIONS OF THE CERVIX UTERI.

AN INVESTIGATION AS TO THE PROPER TIME FOR THE OPERATION.*

DANIEL H. CRAIG, M.D.

Surgeon to Out-patients, Free Hospital for Women; Assistant in Clinical Gynecology, Tufts College Medical School; Editor Annals of Gynecology and Pediatry. etc.

BOSTON.

The following paper embodies the conclusions derived from an investigation covering one year and five months. At the outset all preformed opinions were relinquished and a true spirit of unbiased investigation prevailed. Realizing that it is far easier to teach one wholly ignorant than to controvert preformed opinions, I placed myself in the attitude of a beginner. At the outset I was a partisan of certain operative procedures and certain methods of technic, but this investigation has shown me the narrowness of this attitude. The indications for any certain procedure or technic are inherent in the individual case, not in the predilection of the operator. It is, then, a modest following of the example of Herodotus in that it is "a setting forth of investigation."

As a basis of my study I carefully tabulated the results of one hundred tracheloplastic operations performed at the Free Hospital for Women. A majority of these operations were trachelorrhaphies. This number was selected, as the proportions also represent percentages. Considering two years as a minimum allowance in which to observe the ultimate results of the operation, including its effects on subsequent pregnancies, I began at Jan. 1, 1900, and worked back until replies were received from one hundred women.

So difficult is it to trace these nomadic patients that my one hundred include cases in which from two to five years have elapsed since the operation. Reporting cases under two years would easily have enabled me to tabulate results of several hundred cases, but would have lessened the actual scientific value of the deductions.

My first desire was to prove tracheloplasty a necessary and justifiable procedure. I use the word tracheloplasty, as suggested by Newman in 1898, advisedly, as I distinctly disclaim partisanship to any one procedure.

To consider an operation necessary, symptoms must exist which fail of relief by palliative treatment. To be justifiable, it must relieve these symptoms without endangering the patient's future welfare to a greater extent than does the disease, or it must protect her against a presumably more serious sequel of the above-mentioned symptoms. Except in very exceptional cases, tracheloplasty should be resorted to only after all possible improvement has been achieved by palliative treatment, and this failing, if the operation accomplishes the desired relief it is fair to assume that the operation was necessary. In practically all of these one hundred cases competent palliative treatment had been employed in our out-patient department.

To be justifiable, it must relieve the symptoms, local, referred, and so-called reflex, without causing future sterility, miscarriage or dystocia. Another justification exists if it can be shown to act as a prophylactic of cervical carcinoma.

My first step, coincidently with an extensive research of all reliable recent and much antequated literature on the subject, was the sending of a circular letter to ex-patients requesting answers to the following questions:

THE QUESTIONS ASKED OF EX-PATIENTS.

1. Did the operation relieve your suffering?
2. Have you given birth to any children or had any miscarriages since the operation?
3. How many and when?
4. Was your womb injured by any of these births?
5. If so, how?
6. What is the name and address of the physician who attended you in each confinement since the operation?
7. Have you had any womb trouble since the operation? If so, please state the nature of the trouble.

The following is a summary of the answers received:

QUESTION 1.—Did the operation relieve your suffering? Complete relief resulted in 78 (78 per cent.) cases. Great relief followed in 11 (11 per cent.) cases. No benefit accrued in 11 (11 per cent.) cases. No patient was made worse by the operation. We are accordingly justified in stating that in properly selected cases a properly selected procedure is here devoid of danger; that it is followed by beneficent results in 89 per cent. of the cases. Eighty-nine per cent. of cure or great relief justifies the operation, but this percentage can be materially raised by a more discriminating selection of cases, more thorough palliative preparation and improvement of technic.

QUESTION 2.—This question regarding subsequent pregnancies sought a two-fold enlightenment, namely, does tracheloplasty predispose to sterility or to miscarriage? There were thirty-seven pregnancies subsequent to the operations and of these 24 (80 per cent.) went to full term. Whether any of these 13 (20 per cent.) miscarriages were procured I was unable to learn. Probably a few were. Twenty-three of my 100 women were past the child-bearing period or were widows, which elevates the percentage of pregnancies from 37 per cent. to an actual 49 per cent. Therefore, a proper tracheloplasty does not engender sterility. Moreover, accurate determination of this point is impossible, as most women having undergone one operation, the direct result of injuries incident to parturition, will by every means short of sexual abstinence avoid the possibility of another pregnancy, and such pregnancy occurring will still seek to avoid an operation by seeking early abortion. Twenty per cent., undoubtedly including some procured, is too small a percentage to justify the statement that tracheloplasty predisposes to miscarriage.

QUESTION 3.—This proved almost entirely irrelevant, most ex-patients having had but one child. This fact is due to my receiving more answers from recently operated women than from those of more remote date.

QUESTIONS 4, 5 AND 6.—These questions regarding injuries, their nature and the accoucheur can be considered together, as they coincidently led to much investigation. Only 4 patients were aware that they were relaccrated; definite negative answers were received in 13 instances; 20 failed to answer the question. The fifth question (if so, how?) was irrelevant. Each accoucheur was addressed through a circular letter. All letters reached their destinations, but only 16 of the physicians took the trouble to furnish me with data. On the other hand, several went to great trouble, even visiting and examining patients for me, and to all who answered I wish to express my thanks.

The questions were:

THE QUESTIONS ASKED OF ACCOUCHEURS.

1. Did the cervix dilate easily?
2. Was the cervix relacerated?

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

3. If a laceration occurred should you estimate it as of the first, second or third degree?

Fourteen of sixteen answers told of easy dilatation of the cervix and in 3 instances it was "very easy." In 2 others no dystocia existed, the cervix behaving like that of a primipara. The cervix was relacerated in 8 cases, not relacerated in 7, and in 1 case the physician did not know. Of the 8 relacerations 5 were slight, 3 were of the third degree and in 1 the degree was not recorded. While these numbers are too small to justify broad deductions they at least show that relaceration can not be justly exploited as a serious contraindication when definite indications for tracheloplasty exist.

Question 7.—Sixty-seven women (67 per cent.) have after the lapse of from two to five years been entirely free from "womb trouble." Nineteen of these have sustained labor or miscarriage without recurrence of symptoms. In 8 cases a subsequent labor or miscarriage determined a recurrence of former symptoms. By extra investigation or personal examination I have ascertained that 12 of the 33 not permanently cured owe their symptoms at present to adnexal lesions, fibroids, etc. There has been no instance of malignancy. In 5 instances the recurrence of pelvic symptoms was due directly to traumatism, and, lastly, in 7 cases I thought it possible that the technic might have been faulty. Thus ruling out the 12 non-cervical and the 5 traumatic cases our percentage of recurrences is reduced to 16. Therefore, in properly selected cases a proper plastic operation is capable of being permanently curative, exclusive of relaceration, in 84 per cent. of the cases.

Another fact brought out is that women past 35 are more permanently benefited than those younger. I consider the reason for this to be the fact that they do less hard work than younger women; their children have outgrown the age of being constantly lifted and carried; they are more temperate in all things, including sexual relations, and they seldom have children after the operation at this age.

Having satisfied myself that a proper operation after proper palliative preparation was curative and justifiable, I turned my attention to its prophylactic influence as regards cervical carcinoma. The literature is meager and contradictory, and afforded me no help.

Not facts but locality regulates the expressed opinion as regards the influence of cervical lacerations in predisposing to cervical carcinoma. American authorities so unanimously agree that local traumatism predisposes to future malignancy that the exceptions but serve to prove the rule. In Europe, especially in England, the statement should be exactly reversed.

Laceration and its sequelæ is, we know, not the sole cause of cervical carcinoma, but as we do not yet know even the nature of the remaining factors, we are greatly handicapped in tracing a relation of cause and effect. I determined to learn whether women having had successful tracheloplastic operations were more exempt from cervical malignancy than other women. To this end and also to learn their views regarding relaceration of the repaired cervix, fifty of our most distinguished gynecologists were addressed. In addition, our resident house surgeon, Dr. Bradley, kindly investigated seventy-eight cervical carcinoma cases treated in the Free Hospital for Women. These two lines of investigation cover an enormous, but obviously unknown, number of cases.

After the most careful search of all available records and literature in not a single instance was a history of a previous tracheloplastic operation found in a carcinomatous cervix. Patients contemplating a serious operation on the pelvic organs seldom fail to mention at the very beginning of an anamnesis the fact of a previous operation and few surgeons fail to inquire regarding such. The absence of such history is emphatically significant.

Nearly all specialists addressed responded promptly, a few even writing very instructive letters, and to them all I tender my hearty thanks and appreciation. The following questions were asked:

THE QUESTIONS ASKED OF SPECIALISTS.

1. In what percentage of cases should you estimate that a relaceration of a repaired cervix occurred?

2. What percentage of the total number of cases of cancer of the cervix you have observed should you say had an unrepaired laceration of the cervix?

3. What percentage of the total number of cases of cervical cancer observed by you should you say had undergone previous operations for such lacerations?

The infinite diversity of the answers obtained, defying tabulation, shows that thirty-five years after Emmet's classic paper much need of scientific investigation in this field still exists. The attitude of many of our ablest men also shows that much injury has been done by classing plastic operations as minor surgery. A few admitted the relegation of such cases to their assistants. As a matter of fact, plastic operations require greater technical address than any other. They are less sensational, and to many less interesting than the major operations, but there are many good abdominal surgeons for each good plastic operator.

Question 1.—This elicited answers as follows: Six men express the opinion that no primiparous or repaired cervix ever undergoes the dilatation incident to parturition without at least a slight laceration; the same number state positively that they have never known relaceration to occur after a properly executed operation. Between these extremes are all grades of opinion. Many men of unassailable wisdom and experience answered: "I do not know." Many others stated that they had no data, but that their replies were mere guesses, and, therefore, though fully appreciated, they are useless. From information gathered from all sources, I am convinced that a properly repaired cervix reverts to about the condition of the primiparous cervix as regards laceration. Improper repair may not only predispose to a relaceration worse than the original tear, but like certain unrepaired lacerations, may cause serious dystocia, through containing an excessive amount of cicatricial tissue.

Question 2.—What percentage of cancer cases had unrepaired lacerations? This brought out several replies of: "I do not know." The vast majority estimate them at 75 to 100 per cent. Several obviously confused the question with that of the occurrence of cancer in the nulliparous cervix, and others were stated to be guesses and therefore valueless. Their answers, in connection with my coincident investigation, convince me that at least 90 per cent. of the cases of cervical carcinoma occur in previously lacerated cervices remaining unrepaired. Laceration is by no means a necessary antecedent, nor must carcinoma necessarily follow laceration. If laceration plays an actual etiologic rôle, it is merely as one of an unknown number of factors.

Question 3.—This question, regarding previous tracheloplasty, achieved the nearest approach to unanimity. Fourteen of the gynecologists declared positively that such operation had not been performed in any case observed by them. Many left the question unanswered

and others, confusing the question with that of cancer in the nulliparous cervix or stating that they were guessing without reliable data, estimated the percentage at from 3 to 25. One man stated definitely that cervical cancer was preceded by a tracheloplasty in 6 cases out of 460.

We all know that carcinoma occurs, whether or not as the result of traumatism, in the nulliparous cervix, and it is inconceivable that any tracheloplastic procedure should render a cervix less susceptible to cancer than one never subject to any traumatism. Therefore, I believe that these answers, in connection with the above-cited results of my investigation of all available cases and literature, at least warrant the conclusion that the properly repaired cervix is no more liable to cancer than the nulliparous cervix, and that tracheloplasty is therefore prophylactic of cervical carcinoma. Granting that the operation is justifiable, when indicated, when should it be done?

There are unquestionably a vast number of cervical lacerations which cause absolutely no symptoms and do no harm and in which operation is, hence, not indicated, except perhaps as concomitant of other plastic vaginal operations. Moreover, although the statement has been challenged, it is a fact that many very considerable lacerations of the cervix heal entirely or nearly so by first intention. It is my firm conviction that the cases which heal primarily are not the result of chance, but heal because kept clean and not too badly bruised. Three cases observed at the out-patient clinic are interesting in this connection. All three showed unmistakable evidence of healed cervical lacerations, all denied a tracheloplasty and all three completed the expulsion of their children before the arrival of their attendants, and no examination was made. These facts would probably never have been elicited but for the enthusiasm of this inquiry.

During the past year I have almost daily been able to demonstrate to my students the scars of more or less perfectly spontaneously healed lacerations. Further, surgeons who also practice obstetrics almost invariably get good results from primary operations on the cervix while general practitioners not surgically trained do not. Why? Because surgeons, as no other accoucheurs, can carry out a thorough aseptic technic. A majority of the cases healed by primary operations would heal spontaneously and I know, as you do, that sepsis, not union, will follow the primary suturing of an unclean cervix.

These facts show that in many instances tracheloplastic operations may never be needed. We know that primarily placed sutures, as Hirst has shown, hang like earrings in the cervix after the subsidence of the edema and so do no good, and these data seem to indicate that the primary operation should be reserved for the control of hemorrhage.

If a primary operation is unnecessary for the above reasons, the same is true of the mediate operation. Moreover, Girvan has shown that traction on the ligamentous supports is more productive of uterine prolapse or retroversion at this time than at any other, while Wilcox has shown that for many days following labor the traction and manipulation incident to tracheloplasty is especially liable to cause embolism, possibly septic, from the placental site. The lochia are also troublesome at this period and mediate repair should be reserved for some special indication.

Having passed the above arbitrary periods definite symptoms certainly traceable to the cervix or local physical evidences should be awaited as an indication for operation except the patient be anesthetized for other vaginal work.

As regards tracheloplasty for the prophylaxis of carcinoma, a strict adherence to the above indications is all sufficient. Cervical malignancy begins in the cellular element of the cervix, not in the cicatricial tissue unless the cicatrix has caused cellular inclusions, and so long as these cellular elements remain unirritated as the result of the laceration so long the laceration is doing no mischief. Cancer is, so far as we now know, an uncontrolled, erratic cellular overgrowth due to an ultimate unknown cause or causes. I am convinced that it is through the irritation of these cellular elements on the everted, eroded lips, the seat of the so-called ectropion, that laceration predisposes to carcinoma. Hence if this irritation does not exist, the increased liability to cancer does not exist.

As to technic, a pathologic study of sections from the everted and so-called eroded lips of a cervical laceration shows a decided flattening of the superficial structures. The mouths of the glands, while occluded, are also flattened out. The ectropion which might be termed a pseudo-new-growth constitutes a superficial layer over the deeper and less or unaltered structures. The correct operation for trachelorrhaphy should consist not of an indiscriminate chopping out of the angle of the tear and much comparatively sound tissue by scissors, but of a careful and rational excision of pathologic tissue with a sharp scalpel or specially devised knife.

The symptomatic influence of cicatricial tissue in the cervix has been greatly overestimated in some respects and underestimated in others. Aside from exceptional cases long neglected, cicatricial tissue does its greatest harm in limiting subsequent dilatation. Therefore, so that subsequent dilatation may be free, all excisions of material, especially at the angles, should be done with a knife, which leaves far less scar tissue in its wake than does the crushing out of the scissors.

Tracheloplasty, however, embraces a wider field than is covered by Emmet's operation, and includes the various plastic so-called amputations, Schroeder's operation, and such modifications as have been suggested by Newman, Goelet and others.

In the seven cases early referred to as owing subsequent "womb trouble" to possible error in operative technic, they had displacement apparently or possibly due to too forcible downward traction. All possible plastic operating on the cervix should be done with the patient in Sim's position, thus rendering excessive downward traction unnecessary.

Whenever a repair of the vaginal wall is done at the same sitting, an absorbable suture should be used in the cervix so as to avoid stretching the repaired vagina for the removal of sutures.

CONCLUSIONS.

1. Immediate repair of the cervix is indicated only in exceptional cases aside from the control of hemorrhage.

2. Mediate repair (during continuance of lochia) is contraindicated, except it be in some unusual case.

3. Secondary repair is indicated as soon as symptoms are definitely due to the laceration, such symptoms failing of relief by palliative measures or recurring after apparent palliative cure. Operation should be prompt, not necessarily early.

4. Operations on women past thirty-five give better permanent results than in younger women.

5. Repair of the cervix is indicated as prophylactic of malignancy in a woman approaching the cancer age if the cervix manifests locally evidence of cellular irritation, whether or not causing subjective symptoms.

6. Lacerations in which operation is not indicated should be kept under close observation as the cancer age approaches.

7. Obstetricians are obviously unable to avoid lacerations of the cervix in many cases, but if the above deductions are correct a far more strict asepsis will, by favoring spontaneous primary union of such lacerations, do much toward lessening the number of secondary trachelorrhaphic operations.

158 Newberry Street.

DISCUSSION.

Dr. G. Betton Massey, Philadelphia—This paper represents the methods of investigation that we should apply before forming conclusions. My own conclusions have been necessarily derived from seeing the failures only, and I have seen a great many after late operations. Not being an operator the large number of successes that the Doctor has found in his surgery were not known to me. These failures after the secondary operations were of two kinds: One was failure to remove nervous symptoms. Those cases were very numerous, particularly some years ago when the belief prevailed that all sorts of nervous manifestations in women were due to the existence of a healed scar in the cervix. These healed scars were taken out in many cases, but the patients were not improved. The second class of failures were due to the lack of proper treatment preceding the operative attempts. These patients were really suffering from uterine trouble, but it was a chronic metritis. The scar, which had probably admitted the germs originally, had long ceased to trouble the patient, as was proven by its healing. The subsequent symptoms were due to the enlarged and inflamed uterus, and a failure to cure this before operation probably explains some of the 11 per cent. of cases that were reported as failures. It teaches us that intelligent prior treatment should be exercised in all cases to remove the real seat of suffering, the chronic metritis and endometritis. I conducted a clinic in gynecology for a number of years. Connected with the same hospital were a number of active operators. During the whole time of my clinical work I was anxious to refer as many cases for surgical operation as I could find. Particularly was I looking for laceration cases—cases that in my opinion presented symptoms due to laceration. In the whole time I found but one case that had symptoms due to laceration and not to a metritis. The symptoms were in the nature of miscarriages at a definite period of gestation. The interior of the uterus was normal; there was no leucorrhea, but the uterus was split from the os half way to the fundus. As the patient was anxious to have children I strongly advised an operation. Having absolutely no symptoms from this deep laceration but the miscarriages she failed to take my advice. I want to emphasize the fact that we are looking here at a healed cervix as the cause of symptoms which are either due to the neurasthenic condition of the patient or to an enlarged and inflamed uterus.

Dr. Rudolph W. Holmes, Chicago—Every woman who gives birth to a child at or near term has a laceration. One of the most positive diagnostic signs of a previous pregnancy is that the os is no longer circular, but is generally a transverse slit. We must consider that a laceration is physiologic because every woman has it. We can call it pathologic only when a train of symptoms is produced. Women may have a laceration extending to the vaginal vault and it will be physiologic unless pathologic conditions are caused by it. I would like to ask what are the symptoms of a laceration. I have never heard of them and I do not believe that they exist. The symptoms are not those of laceration, but symptoms of the conditions produced by the laceration, such as sepsis or relaxation of the pelvic floor, which commonly accompanies the cervical laceration. From the obstetric standpoint I condemn the promiscuous repair of lacerations of the cervix. No laceration should be repaired unless there are symptoms of the sequelæ of the laceration and when tentative measures fail. I can not recall one case of obstetrics in which a previous trachelorrhaphy had been done where there were not anomalies in the dilatation. As opening of the os occurred it invariably took place, not from dilatation alone, but with concomitant laceration. The most severe cervical lacerations with the accompanying hemorrhages that I have ever seen in my practice have been in cases where a trachelorrhaphy was done subsequent to a previous labor. Of course, we can predict that a woman who has an immense amount of cicatricial tissue in the torn cervix will have an extension of the laceration in her subsequent labor. Furthermore, in taking up the statement that carcinoma is more frequent in parous women because they have had cervical lacerations, and that the repair of lacerations will serve as a prophylactic measure, seems to me to present a great deal of sophistry; this assertion can only be conclusively demonstrated when a large series of cases of carcinoma are taken, and those who have not had trachelorrhaphies are compared with those who have had the operation. Further, I believe desirable results will be obtained for a working hypothesis if all the non-parous women who die after thirty years of age are compared with the parous in the same period of life; 90 to 95 per cent. of all malignant growths of the cervix are in parous women. Is this far from the percentage of parous women in relation to the non-parous at the time when cancer is prone to occur? Lacerations often heal spontaneously if no infection occurs to retard the reparative process. In some instances it is well-nigh impossible to tell if there had been a laceration because the union is so perfect; that is, there is a mere nicking on one or both sides of the external os; if these cases had been examined immediately after labor a considerable degree of laceration would have been demonstrable. I have verified this statement on a number of occasions, for I always examine the parturient canal after operative labors to ascertain the damages done, and again an examination is made at the end of two months. The reason why lacerations are generally found laterally is not explained alone by the fact that tears almost invariably occur there; tears very frequently are in other quadrants of the cervix; in the latter cases the opposing bladder and rectum act as a sort of splint; in the former this splint action is of no avail, and the movements of the uterus with the respiratory excursions prohibit primary union.

Dr. A. M. Hayden, Evansville, Ind.—We have lacerations that require repairing, and some that do not. If we have a laceration heal, with an inflamed cicatricial scar, that should come out. Endometritis is often directly due to that, and by removal of the scar the endometritis is cured. If we have a laceration that has healed with no inflammation, no endometritis, then, no matter how deep the laceration, there is no indication for an operation. That patient will bear children as well as if she had no laceration. But we find many cases that have nervous symptoms and pain in the pelvis, and we find a laceration that never healed, with endometritis; then we should operate. The patient promptly gets well; the endometritis subsides without further treatment, and there are no further symptoms. Those cases all require operation. I have had many cases of carcinoma of the cervix and I have yet the first case to see where the carcinoma did not follow a laceration of the cervix.

Dr. C. S. Bacon, Chicago—The attempt of Dr. Craig to get definite data on this question of operation is to be commended, but I do not believe he has secured enough data to justify his conclusions. In the main I believe that most obstetricians would agree with Dr. Holmes. I will agree with Dr. Craig concerning the immediate repair of a laceration if he will make one addition to his conclusion, viz.: That immediate repair is important when there is a deep laceration extending up into the musculature of the uterus for some distance after a severe obstetric operation. It is well known that rupture of the uterus is much more common in cases where there has been a rather serious injury of that kind, and in those cases there should be a careful restoration by suture.

Dr. F. A. Dunsmoor, Minneapolis—Physicians criticise these operations because they hear stories of trouble from the failures, from the ones who suffer pain. The cured patient does not go to every dispensary and physician she knows and tell him that she was operated on and benefited. The patients who go around to the dispensaries, hospitals, etc., are rounders, who are never satisfied. They always criticise the surgeon because he failed to cure them of all their ills. This is the reason we hear so much about the failure of operations, and so little of the successes. Let us announce the results of the operations in patients who have been cured. Dr. Holmes does not believe that a laceration *per se* is a cause of cancer. I differ with him. I have operated on more than a hundred women for cancer of the uterus and all had borne children. Take into consideration the number of women who bear children and have a laceration, and those who bear children but do not have a laceration, and it is the non-repaired laceration which is productive of cancer. I have never yet had the opportunity to operate on a sterile woman for cancer of the uterus, although others claim they have. This repair operation is prophylactic for many conditions not cancerous. Women with deep lacerations of the cervix are predisposed to prolapse, endometritis and dragging pain associated with rectocele and cystocele, and early repair prevents the sequence. As to the diagnosis of laceration, Dr. Holmes says it can not be made except through the speculum. I differ with him again. I can certainly make a diagnosis much better with the point of my finger than by inspection. Often the eye says it does not look like a pathologic condition, but the tactile sense discovers it. I had an interview with Dr. Emmet about ten years ago, and at that time he reported two troubles. One was his renal colic, and the second was from people who thought they made an Emmet operation, when really they did something far different from his conception of it. He said he was often sorry that he ever described that operation because it had been abused so much. It is the experienced operator to whom we turn for counsel in this matter, and I am sure that all lacerations of sufficient extent to be shown by examination through eye or touch as a possible seat for future disturbance should be repaired at first opportunity.

Dr. D. H. Craig—Had I trespassed on your time sufficiently to read the remainder of my paper some of the criticisms brought out in the discussion would have been answered. As regards scars in the cervix, there is one important question in the technic of the operation. When the denudation or removal of the diseased tissue is made with scissors you leave behind more scar tissue than necessary. I believe that it is important that we remove this pathologic tissue, not by scissors, but by the knife, whether specially devised or the ordinary scalpel, so that we can have accurate coaptation and leave a minimum amount of scar tissue in the cervix. Remove it as you would any new growth; not by indiscriminate cutting out of healthy tissue through a circular sweep of the scissors. The symptoms of laceration were considered at length in my paper. I consider the symptoms of a laceration of the cervix sufficient justification for an operation when other causes of the symptoms have been ruled out by proper previous treatment. I do not mean that cervices should be indiscriminately operated on, but we should select our cases and also the procedure which must be adapted to the individual case. No one operation will answer for all cases.

The successful physician is usually the man who attends strictly to his own business, and refrains from intruding into the affairs of others; who speaks kindly of his fellow practitioner, whether he deserves it or not; who is studious and observant, and profits by his own and the experience of others; who is full of good cheer, and is competent to give wholesome advice. If all physicians belonged to this school the medical profession would be a mighty power, capable of engineering mighty plans for the good of the people, united and respected, free from unjust criticism, and possessed of more than a "common mind."—*Northwestern Lancet.*

ACUTE GENERAL STAPHYLOCOCCUS INFECTION THROUGH THE PUERPERAL BREAST.*

W. P. MANTON, M.D.
DETROIT.

One of the most important functions devolving on the accoucheur is the management of the nursing breast, a responsibility too often shirked, either from indifference, carelessness or ignorance of the physiologic processes involved—a deviation from which may give rise to great physical suffering and lead to disastrous consequences.

It is now universally conceded that all of the more serious disorders of the functioning mammary gland are the result of microbic invasion, the morbific germs gaining entrance to the lobes and interglandular connective tissue either through the ducts, more rarely, or generally through cracks and abrasions of the nipples and surrounding areolæ. Septic material may readily be conveyed by the hands of the patient or an untidy nurse to the wounded surfaces, while the increased vascularity of the breasts and their augmented lymphatic circulation during the inauguration of the secretory function render these glands peculiarly susceptible to the influence of the materies morbi. Moreover, the researches of Honigmann, Ringel and Kostlin[1] have shown that normal human milk contains both varieties of the staphylococcus, while Escherich maintains that pathogenic germs which have gained entrance to the blood from diseased puerperal organs are excreted by the breasts in the milk—additional evidence as to the necessity for the closest surveillance of the breasts during the whole of the lactational period, and especially during the early stages of beginning glandular activity.

While much may still be said and written regarding cleanliness, asepsis and the general care of the healthy and disordered mammary glands during lactation, it is not my purpose to review these phases of the subject, the sole object of this short paper being to direct attention to a single method of treatment much advocated and in vogue, but which, if misdirected, is capable of producing most serious complications. Take up any of the latest text-books on obstetrics and turn to the chapter on the puerperal breast and you will find that, with one exception (Garrigues), massage is recommended in the treatment of mammary engorgement and beginning mastitis. But nowhere will you find a warning word against the possible dangers which may arise from this practice.

The following case illustrates my meaning:

Mrs. T., primipara, aged 18, white, married and a native of Canada, was delivered at the Woman's Hospital by low forceps after a somewhat tedious labor, March 28, 1902. The male child weighed eight pounds. The placenta was expressed twenty minutes after the delivery of the child, and was of unusual size, weighing two pounds and thirteen ounces. The cord was twenty-four inches long and had varicose vessels. There were no maternal lacerations.

Two days later (30th) the patient complained of sore nipples, but the temperature and pulse remained practically normal. On the evening of the third day the temperature suddenly rose to 102.4 and the pulse to 104. There was no chill and the

1. The latter found micro-organisms, generally staphylococci, in the milk of 91 per cent. of puerperæ. Archiv für Gynäkologie, Bd. liii, 112.

patient appeared in good condition, save that the breasts were tumefied and painful from beginning lactation.

April 1. The temperature was still high and the breasts hard and knotted. Massage with warm olive oil was given in the forenoon and again in the afternoon, and the breast bandage applied.

April 4. The temperature being still much elevated, higher than the condition of the breasts appeared to account for, a careful pelvic examination was made with negative result as to abnormal conditions. A culture taken from the cervical canal at this time was reported by Mr. Tibballs, bacteriologist to the Detroit Board of Health, to be free from pathogenic organisms. The breasts were still sore and painful and massage was continued twice a day, as is customary in such cases in this institution.

April 8. The chart records that the breasts were massaged at 7 and 10 a. m., and again at 4 and 7 p. m. A second culture taken from the cervix was found to contain a few staphylococci and micrococci. As it was evident that the breast massage was being executed in too vigorous a manner it was ordered discontinued. On the following day the patient complained of pain in the left thorax and side.

April 9. An examination of the blood by Dr. Heneage Gibbes showed the absence of micro-organisms. There was slight leucocytosis with polymorphonuclear cells in excess. The blood platelets were disintegrating and did not take the stain in a normal manner.

April 10. The patient had a very offensive, free, watery stool, containing particles of undigested milk. A cough also developed which gave rise to considerable distress, and it was feared that septic pneumonia might be developing, but careful examination showed the lungs to be unaffected.

Fluctuation was for the first time detected in the right mammary gland, and a large parenchymatous abscess was evacuated under chloroform. The pus examined by Dr. Gibbes was reported as follows: "This pus is made up of broken-down material and contains large numbers of staphylococci. There are also a few tetrads. The micro-organisms take the stain faintly and are not in an active condition."

April 19. An abscess appeared in the left breast and was evacuated by incision. A red spot was also discovered near the middle of the patient's back. This subsequently gathered and discharged for several days.

April 23. A second abscess developed in the left breast and one in the right arm.

May 4. An abscess appeared in the right buttock.

May 8. The patient sat up for the first time, the abscess still discharging but gradually healing.

May 27. Another abscess developed in the left breast.

From this time on no new abscesses were formed; the temperature and pulse gradually returned to the normal, and the patient left the hospital well, but still weak from her serious illness, June 5, seventy days from the date of her confinement.

At the beginning of the infection there was more or less gastric irritability and on several occasions vomiting, but as a rule the stomach remained in good condition and the patient took a fair amount of nourishment. Almost from the first the nervous symptoms were pronounced and delirium occurred on the fourteenth day. The patient became noisy and hallucinations of sight and hearing developed. These manifestations persisted more or less for several days. The general condition varied from day to day; the temperature ran an erratic course, fluctuating from normal to 105.6, the highest point reached during the course of the disorder. The pulse rate varied between 76 and 126. The child did poorly from the first, and died on the twelfth day of inanition.

Acute general staphylococcus infection through the puerperal breast is a rare affection, and the case reported is the only one of the kind which I have met in an experience of several thousand midwifery cases. In a fairly careful scrutiny of the literature of the past ten years, I have been able to find but one other somewhat similar instance reported, and in this the pathogenic organisms were streptococci.[2]

2. Max Bensiger: Centralblatt für Gynäkologie, No. 52, 1902.

But however uncommon the condition may be, the case just related stands as a vigorous protest against the indiscriminate employment of massage in mammary engorgement during the early days of the puerperium. Distension and turgescence of the nursing breast can be better and more safely treated by other means, and the dangers of traumatism to the congested and often exquisitely sensitive organs and the formation of mammary abscess together with the possibility of septic infection may thus be obviated.

DISCUSSION.

DR. CHAS. S. BACON, Chicago—Infection of the breast with staphylococci or streptococci certainly is not very rare; nor is a general infection from that source rare. Massage of the puerperal breast is a subject I have talked and written about for the last four or five years, but I do not seem to make much impression. We should distinguish between turgescence or congestion of the breast at the beginning of lactation and infection, but usually that is not done. Very often a large, swollen, overfilled breast is called an inflammation. On the other hand, in the inflamed breast the infection often is not recognized unless the symptoms are very distinctive. The place for massage is the non-infected breast; I would not dare to use it in an infected breast. When there is fever or other symptoms of infection massage is absolutely contraindicated. There support and ice are indicated until the presence of the abscess is determined. When the breast is full and swollen at the beginning of lactation it does not mean that the breast is full of milk; it is an overfilling of the blood vessels. I can make the breast soft and small and not evacuate more than a drop of milk, but the massage must be carried out in accordance with the ordinary principles of massage, and these are not ordinarily taught. You have all seen pictures where massage is done by rubbing toward the nipple. That is absolutely false. The object of massage is not to evacuate the milk, but to empty the overfilled blood vessels and lymphatics. In a congested knee joint you do not rub toward the knee; on the contrary, you rub away from the knee, first emptying the blood vessels before you approach the tender joint. You must begin outside of the breast and empty the vessels leading to the axilla and the subclavian veins and lymphatics. That can be accomplished without pain to the patient. The criterion whether massage is done properly is when the operation is not painful. The manipulator must sit in a convenient position; have sterile hands, place his patient in proper position, and begin outside of the breast, gradually coming nearer and nearer to the nipple as he empties the vessels. In fifteen to twenty minutes the breast is small and soft. How many cases need that massage? Not very many. Nor is it absolutely necessary in any case, because overdistention of the breast is never a serious matter. But a nervous patient who is weak, who has suffered a hard confinement and has this very tender breast, may lose many hours of sleep and rest; if that can be prevented it should be done. One or two such treatments will usually suffice to give relief.

DR. EFFA V. DAVIS, Chicago—For many years I have had a great fear of massage of the breast and also the use of the breast pump. Staphylococci as a cause of infection in the breast is interesting. All of the open glands on the skin surface are likely to be contaminated, and I believe the massage in this case produced the abscess. Infection of any part of the body, the pelvis or elsewhere, is likely to affect the mammary gland as the turgescence offers a good lodging place for bacteria. I warn my patients and nurses to let the breast alone. A bandage is applied smoothly and evenly on the evening of the second day; this minimal pressure reduces the turgescence somewhat and the child is put to the breast on the first day after delivery. If one uses a bandage properly adjusted instead of the rubbing process the natural turgescence will not be troublesome.

DR. RUDOLPH W. HOLMES, Chicago—Dr. Bacon has done a great thing for the profession in exposing that nonsensical massage so commonly recommended in obstetric text-books; he

did a far greater good when he described a method of massage for the breast which was based on sound anatomic reasons. Massage should not be done indiscriminately; it should only be done on an engorged, tender breast. It is almost criminal to continue the manipulations when inflammation has occurred. Then, too, I think the nipple should be better prepared, not by using hardening solution, such as alum, which I believe tends to promote fissures, but by using an oily preparation, such as cacao butter impregnated with some mild, innocuous antiseptic like boric acid. These two suggestions, Bacon's massage and preparation of the nipple, will go a long way toward preventing such complications as were described by Dr. Manton; massage will often disseminate a local process into a systemic disease. Further, a well applied binder is a useful adjunct. I do not believe that staphylococcic infection of the breast is so infrequent; this presumption is based on the myriads of these germs normally found in the skin. Undoubtedly it is more rare to have a systemic infection originating from a mammary contamination. The question naturally arises if the massage in the early part of the treatment might not have been a factor in the later course of the disease.

DR. W. P. MANTON—I do not believe that general staphylococcic infection is uncommon, but I can not find any record of cases.

THE MORPHOLOGY AND BIOLOGY OF THE PARASITE FROM A CASE OF SYSTEMIC BLASTOMYCOSIS.*

F. J. OTIS, M.D.
Instructor in Bacteriology and Hygiene, and
NEWTON EVANS, M.D.
Instructor in Pathology, American Medical Missionary College.
BATTLE CREEK, MICH., AND CHICAGO.

The observations recorded in this paper were made on the parasites obtained in the tissue and by artificial culture from the case of fatal systemic blastomycosis reported by Ormsby and Miller.[1] We wish here to acknowledge their assistance in the work done and kindness in allowing us to use the material from their case.

In May, 1894, Gilchrist[2] described in tissues from a skin lesion the spherical, double-contoured, budding microörganisms which have since been observed in about thirty-five reported cases. In this case cultures were not made and little was known of the biology or nature of the parasite. In November of the same year Busse[3] reported a case of systemic infection resulting fatally in which a similar parasite was described as the etiologic factor. Cultures were made from this case and the organisms extensively studied by Buschke.[4] In culture the organism grew by budding, and mycelial formations were also seen.

The cases reported have had lesions for the most part confined to the cutaneous surface. A few cases of systemic infection, however, have been observed. The cases have largely occurred in the United States. The largest number have been observed in and about Chicago. The cutaneous lesions have characteristics which show such uniformity that they may be distinguished often by their gross appearance. The microscopic findings are similar in all cases, and the presence of the typical organisms in the tissue, or pus of miliary abscesses, is pathognomonic. The cases of systemic infection, as far as we can determine, which seem to have definite confirmation, are four: First, the case of Busse and Buschke; second, a case reported by Montgomery and Ricketts,[5] and later by Walker and Montgomery;[6] third, one reported by Ophüls and Moffit[7] (San Francisco), identical with those cases which have heretofore been called a protozoan infection, but which was proved by him to grow as a typical fungus in artificial media; and lastly, the case of Ormsby and Miller,[1] in Chicago, from which our material was obtained. All of these systemic cases have resulted fatally.

There is much uniformity in the morphology of the organism, as found in the tissues and purulent exudate, in all these cases, both cutaneous and systemic. They are spherical or oval, double-contoured, with very refractive cell capsule, increase by budding, and, in the Ophüls' case by sporulation, which has not been definitely proved in any other case. No mycelia are found in the tissues or pus. The size varies within wide limits in different cases, parasites from three to thirty microns in diameter being seen. The cultural characteristics of the organisms from different cases show marked variations, in some cases multiplying by budding exclusively, in others growing mycelia principally, and in others abundant aërial hyphæ are produced. Hektoen[8] describes very minute forms which, under proper conditions, develop into the larger form. And, further, some of the organisms, if watched for some time through a number of generations of growth, completely change in their characteristics on artificial media, multiplying at one time by gemmation, and afterward forming mycelia, or vice versa. We may thus say that in its growth and cultures, polymorphism is manifested to a striking degree. Hektoen made a careful study of the parasites from a case of blastomycetic dermatitis.[8] He describes the appearance of the different forms of the organism as seen in the tissues; some with a clear zone surrounding the protoplasm inside the capsule, others in which this is inconspicuous; some with large vacuoles in the protoplasm, others with dense, granular protoplasm without vacuoles. He also describes mulberry-like masses of hyaline bodies in the tissues, both intracellular and extracellular. The cultural forms varied much in size, a small, coccus-like form being described.

Gilchrist[9] makes extensive observation on the morphology and biology of the parasite. The process of budding, as it occurs in the tissue, is accurately followed. The endosporium, or protoplasm, of the bud increases to almost the size of the parent, and then becomes separated. He also notes peculiarly refractive forms which will not take the stain. Other forms in

which the protoplasm has contracted into a half-moon shape are described. The adult forms in cultures show in the protoplasm fine, deeply-staining granules, larger refractive granules, and often one or more vacuoles.

Ricketts[10] has collected and tabulated observations concerning the morphologic, biologic and cultural characteristics of the organisms from a number of cases (seventeen), from which table he concludes that there are three more or less distinct groups of organisms having common generic characteristics. Montgomery[11] gives a very careful description of the clinical, pathologic and bacteriologic features from thirteen recorded cases.

DESCRIPTION OF CASE.

The clinical history and discussion of the present case have already been reported by Ormsby and Miller,[1] accompanied by a brief description of the microscopic and gross pathology of the tissues affected, and also a short study of the cultural characteristics of the organism by the present observers. The history indicated that the primary infection was located in the pulmonary tissue, followed by the cutaneous and subcutaneous lesions. Practically all the cutaneous lesions were of such a nature as to indicate the hemal origin of the infection, the superficial tissues being affected only after the process progressed from the deeper tissues. One lesion only, on the hand, had the characteristics described in the lesions of blastomycetic dermatitis of local origin. Of the internal organs, the lungs were most extensively involved; grayish nodules of varying size, and in enormous numbers, being distinguished in all parts of the tissue of both lungs. The pleuræ were extensively affected, and adhesions and whitish nodules of varying size were present in all portions. The lesions in the spleen were almost as extensive as in the lung. The nodules composed of typical organisms were found also in the liver, kidneys, pancreas, trachea and larynx. (This is apparently the first case in which involvement of a mucous membrane proper has been described.) The teased specimens in hanging drop from the different organs gave abundant opportunity for studying the living parasites as they occurred in the lesions. The stained sections from the lung tissue, especially, show parasites in immense numbers.

MICROSCOPIC APPEARANCE OF TISSUES.

Lung.—The slight degree of inflammatory reaction is noteworthy, the lesions being composed almost entirely of the parasites. There is some newly-formed connective tissue containing small round cells, polynuclear leucocytes and many mast cells, the protoplasmic granules of which stain red with polychrome methylene blue. There is some coagulation necrosis, areas of caseation appearing mostly at the center of the nodules. In the areas where the parasites are very abundant the elastic tissue has entirely disappeared, as indicated by staining with orcein. The epithelial cells which are remaining in the lung are largely detached, and are remarkable for the amount of brownish pigment granules which they contain. Similar deposits of pigment are found in many other cells, especially the polynuclear leucocytes of the blood.

The giant cells in the lung tissue are remarkable for their number and size. They vary from twenty microns to many times that diameter. They all contain parasites in different stages of development, and the larger ones are crowded with them, the cell nuclei being few and indistinct, while in the smaller giant cells the cell nuclei are numerous and prominent. The peripheral arrangement of the nuclei seen in the tubercular process is not followed, but many of the nuclei are near the center of the cell body.

Spleen.—The splenic tissue is riddled by the growth of the typical organisms, showing grossly as yellowish-white areas and nodules. Microscopically, the parasites are seen scattered widely throughout the tissue, but not in such large masses as in the lung tissue. The splenic pulp contains much brown pigment.

The lesions of the kidney, liver and pancreas are smaller and less numerous, often escaping naked eye examination. The immense numbers of parasites and small amount of newly-formed connective tissue are the principal characteristics of these lesions. In and about them are always seen typical mast cells.

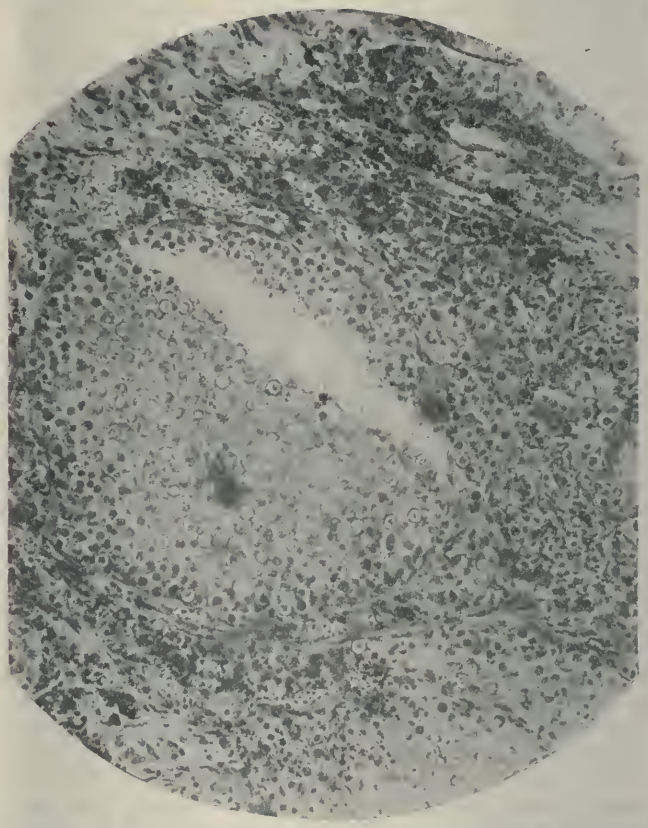

Fig. 1.—Nodule of blastomycetes in lung tissue. Center showing old, poorly-staining organisms, and periphery showing young, deeply-staining organisms.

Lymph Nodes.—The peribronchial lymph nodes were markedly enlarged, and contained large amounts of black pigment, apparently carbon. On microscopic examination we were unable to demonstrate the presence of any parasite in the tissues; however, in one section parasites were seen in the blood stream of one of the vessels.

MORPHOLOGY OF PARASITES IN THE TISSUES.

The stained sections of lung tissue offer excellent opportunity for a study of the parasites in different stages of their development. There are seen large, rounded masses of parasites under the microscope (Fig. 1), at the center of which the organisms are all of large size, take very little stain, show few buds, and many contain large vacuoles, occupying almost the entire cell. These are evidently old cells which are degenerating and disintegrating, as indicated by the granular detritus

11. Montgomery, F. H.: A Brief Summary of the Clinical, Pathologic and Bacteriologic Features of Cutaneous Blastomycosis, THE JOURNAL A. M. A., 1902.

among them. At the periphery of these areas the organisms differ much from those at the center. The cells are of various sizes, have deeply-staining protoplasm and are undergoing cell division actively. These areas, therefore, give excellent opportunity for the study of the life history of the parasite in the tissue.

The most satisfactory stain which we have found for studying the structure of the yeast-like organism is the polychrome methylene blue stain, applied according to Unna's method. Other stains used are hematoxylin and eosin, methylene blue and eosin, Gram's stain, Van Giesen's method, carbol fuchsin and orcein.

The typical parasites are of various sizes, measuring from five to fifteen microns in diameter. They all have a definite, refractive capsule, which takes most stains sparingly, usually less than one micron in thickness. The capsule stains best by methylene blue and eosin. Within the capsule the structure has so many variations as to be almost picturesque in the variety of forms seen. Many of the cells have a wide, clear zone within the capsule and surrounding the protoplasm.

In the natural order of growth of any organism, one expects to find a certain definite order of development, and it has been our effort by careful study of the various

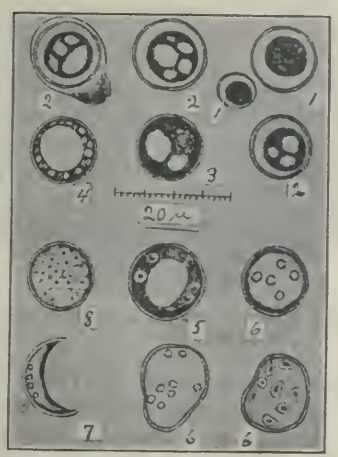

Fig. 2.—Diagrammatic representations of adult forms of parasite showing different stages of development. (Made from drawings.) 1. Young forms, dense protoplasm, wide clear zone. 2. Protoplasm vacuolated; one enclosed by tissue cell. 3. Protoplasm fills capsule. 4. Contains one large vacuole. 5 and 6. Contain spore-like bodies. 7. forms to determine the characteristics of the cells at the different stages of their development. We see, then (Fig. 2), in all forms a capsule protoplasm of varying structure and staining properties; in many the clear space between the capsule and protoplasm, and many contain one or more vacuoles of various sizes. Budding forms are numerous, and cells of almost all types of structure are seen undergoing this form of multiplication; but the budding process is most active in cells of a certain type—those in which the protoplasm is dense, deeply staining and relatively small in amount, being surrounded by a wide, clear zone. These are of medium or small size generally, and are evidently relatively young and actively growing forms. We can distinguish, then, the following types:

1. Cells which are small in size, from five to ten microns usually, having a relatively small mass of deeply-staining protoplasm, surrounded by a wide, clear zone inside the capsule. The mass of chromatic substance is spherical, except in those which are undergoing the budding process, is centrally or excentrally located, is finely granular or homogeneous, but very deeply stained. Many of these are budding.

2. Forms similar to the first, but slightly larger on an average, the deeply staining protoplasm being more coarsely granular and containing clear, rounded spaces, which are evidently vacuoles, of varying size and number. The protoplasm occupies a larger area in the cell, the clear zone being narrower than in the preceding form. Many of these are undergoing the budding process.

3. Forms similar in size to the preceding, protoplasm staining well, granules large, a few large vacuoles being present, all of the space occupied by the protoplasm, the clear zone being obliterated or inconspicuous.

The preceding forms are found especially at the periphery of the circular masses of parasites described in the lung tissue, and are evidently younger and growing forms, actively dividing.

4. Large cells in which the protoplasm fills the capsule and contains a single, very large, spherical vacuole, centrally or peripherally located. The protoplasm thus appears as a ring of granular material, does not take a deep stain, and some small, circular, hyaline areas are seen in it. These forms are seen mostly at the center of the masses of parasites.

5. Large forms with very large central vacuole, a thin layer of protoplasm which has undergone division into spore-like bodies, which have the appearance shown in the figure. These bodies are about one micron in diameter, appear to have a central clear space surrounded by a ring of chromatic substance of irregular thickness, the chromatic substance often being accumulated at one portion of the ring, at other times appearing as two masses on opposite sides of the ring. These spore-like bodies are seen to be only at the periphery of the cell capsule. These forms of cells are found only at the center of the masses of parasites.

6. Similar cells in every respect, except that they are collapsed, the fluid contents of the vacuole having been evacuated. These forms are evidently derived from those described in paragraph No. 5. Very few of those cells with refractive contents have undergone any such change.

7. Another distinctive form appears in which the protoplasm contains no large vacuole whatever, but as they develop the protoplasm divides into from ten to fifteen small hyaline bodies, in many of which is seen a central densely staining body. Similar bodies to these are also seen outside the capsule.

Other variations in the structure of the cells may be seen—some with refractive contents which does not take the stains; others are seen in small numbers in which the protoplasm is completely obscured by a mass of brown pigment. The presence of these forms is possibly an explanation of the origin of the pigment granules described in the tissue cells, and in the leucocytes of the blood. With polychrome methylene blue stain a great many of the organisms contain in their protoplasm basophilic granules staining red. These have been described by Gilchrist and others. There is a remarkable variation in the affinity which different organisms have for the stains, cells lying side by side, and apparently of the same structure, show an entirely different reaction to the stain. Several observers have described adventitious capsules. We have not observed a similar condition, but often individual parasites are seen within the protoplasm of the tissue cells, which is stretched about it and so attentuated as to resemble a capsule.

SPORE FORMATION.

Multiplication of the organism by budding is the usual method within living tissue, and by budding and mycelial and conidial formation in the culture, but the production of endospores and propagation by their development is still a matter of doubt. In the case under consideration the findings in the tissue seemed to indicate the presence of spore formation, and we will endeavor to describe this process here (Fig. 3). These forms occur for the most part in the centers of the masses of parasites where all the organisms are of advanced age, and many are disintegrating. Most of the cells in question contain large central vacuoles, the protoplasm being pushed to the periphery, appearing as a ring just within the capsule. This ring of protoplasm has undergone division into bodies which are small (about one micron in diameter), and are composed of an outer ring of chromatic material and a hyaline center (Fig. 4). These bodies have already been described in a preceding paragraph. These spore-like bodies are seen by careful focusing to be situated at the periphery and not at the center of the cells, the center being occupied by a large vacuole. They number from eight to twelve in a capsule. Exactly identical forms are seen as ex-

Fig. 3.—Sporulating forms and developing spores. 1 and 2. Adult forms containing spores. 3 and 4. Extracellular spore bodies; one at 4 is situated in protoplasm of tissue cell. 5 and 6. Developing spores. 7. Crescentic forms of developing spores. 8. Organism from guinea-pig's kidney, sporulating.

tracellular bodies, and other larger forms which have a crescentic shape and have evidently been formed by the development of these ring-like bodies, the chromatic substance increasing on one side and the hyaline center becoming eccentric, thus producing the appearance of a crescent. Further, there are found in these old capsules just described other small forms having a solid chromatic center surrounded by a hyaline area, and similar to the bodies appearing in the cells which we will now describe.

There are certain cells which we have already mentioned which do not contain vacuoles, at least have no large central vacuole. In their later stages the protoplasm of these forms breaks up into small rounded hyaline bodies, many of which are seen to have a densely stained spherical center. Bodies exactly resembling these are seen outside the cells, and others, which are larger, one to three microns in diameter, and having about them the hyaline zone, but no distinct capsule as seen in the adult form. Some of these forms have been noted within tissue cells, and these tissue cells with their contained spore bodies are probably the beginning of the giant cells. As soon as these developing spores reach a size of about four or five microns a capsule is seen surrounding the clear zone. It was noticed that the parasites which are in the younger and smaller giant cells are mostly the smaller forms, while the older and larger giant cells contain older developmental forms of the parasites. It seems probable that the large rounded masses of parasites described in the pulmonary tissue are the result of further development of the giant cells.

The sporulating forms described here differ radically in the number of spore bodies formed within one capsule

Fig. 4.—Showing spore-like bodies in disintegrating capsule (just above the center of the field).

from the corresponding forms described by Ophüls in his systemic case, also from the forms pictured by Gilchrist.[12] They contain usually not more than twelve or fifteen, while Ophüls describes one hundred or more in each cell. However, we have noted in one of the

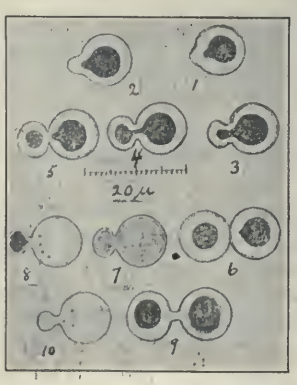

Fig. 5.—Budding forms. 1 to 6. Series showing progressive changes in process of gemmation. 7 to 10. Unusual forms. 8. Organism, budding and apparently sporulating simultaneously.

guinea-pigs experimented on forms containing a very large number of spore-like bodies.

We have, then, two forms of cells producing spore-like bodies, one with a large central vacuole and one without, the bodies produced in these two forms being different in appearance, as already described. In no case

12. Gilchrist, T. C.: Blastomycetic Dermatitis in the Negro, Brit. Med. Jour., Oct. 25, 1902.

have ruptured forms been observed in the tissues, the spores apparently being liberated by the disintegration of the parent organism. There is a possibility of confusing some of the extracellular developing spores with certain products of tissue cell degeneration.

We have not absolutely observed the development of these spore-like bodies into adult organisms, but the appearance of the different forms which we have seen in the tissues leads us to believe that this is really the case.

THE BUDDING PROCESS.

The process of budding, as observed in the tissue sections, is almost entirely confined to the younger forms, those having deeply staining protoplasm and a wide, clear zone within the capsule. However, it is seen in other forms. A few cells are seen undergoing gemmation and apparently sporulation simultaneously. The different stages in the budding process are represented by a series of drawings in Figure 5.

CHANGES IN THE BLOOD.

In the case of Busse,[3] where there was a fatal systemic infection, cultures of the parasite were made from the blood during life. In Gilchrist's case,[12] which he regarded as a beginning systemic invasion, examination of the blood by culture failed to reveal their presence. In the case under consideration, we have observed in the blood stream of vessels of the kidney (Fig. 6), also in other places, adult parasites mingled with the blood cells. On examination of sections of a postmortem clot from the heart practically all of the leucocytes were seen to contain large, brownish pigment granules of uniform size, from three to ten in a cell.

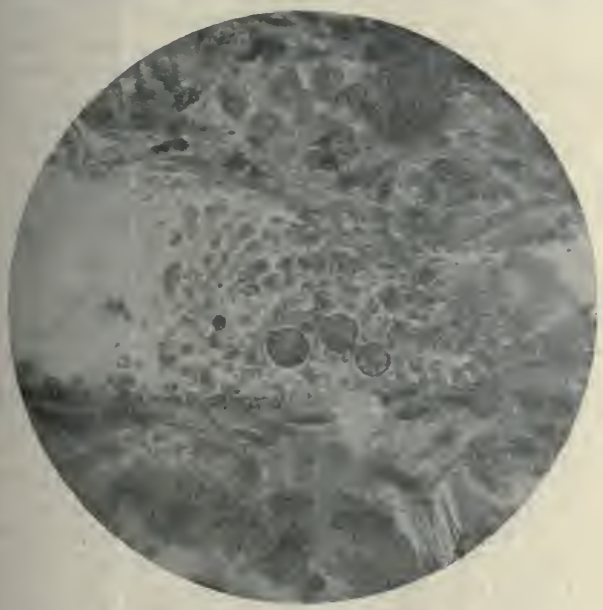

Fig. 6.—Three adult parasites seen in the blood stream of a vein of the kidney.

TEASED TISSUE IN HANGING-DROP CULTURE.

In the teased specimens of fresh tissue from the affected organs large numbers of blastomycetes were observed. They were not all of uniform size and structure. They varied from five to fifteen microns in diameter. The contents of the cell were often nuclear in appearance. Sometimes there were only granules present. Frequently the granular contents were lobular in appearance. raspberry-like; again, they would assume a circular form about a large vacuole.

The cell wall is refractive and perfectly spherical. There is frequently one point where the capsule appears very thin, a point at which the protoplasm is often seen to protrude in the budding process. This is not always the point through which the growth takes place, for budding cells have been observed to produce mycelia from a point at sufficient distance from the point of attachment of the daughter cell to subtend an angle of twenty degrees. At the point where the mycelium appeared the capsule appeared to be perfectly firm.

Cell Development.—When hanging-drop cultures were first made, the cells varied considerably in size, but in a few days they had all reached a uniform size. As far as could be observed, no new budding processes took place after the cells had been placed in artificial media. Buds already existing grew to full-sized organisms. Some time later there appeared a few very large organisms (twenty to thirty microns in diameter) that changed their form from round to oblong. None of these large forms developed mycelia. In old mounts the cell contents of most of the organisms developed oil-like globules that varied from one to seven microns in diameter. In ten days some of them became so large that one globule occupied most of the cell. Some granule-like bodies manifested a very marked brownian movement. The formation of the fat-like globules seemed to be a process of degeneration, for the cells most exposed and those supplied with the poorest pabulum developed the largest globules.

Fig. 7.—Blastomycetes. Teased cells from spleen beginning development in artificial media.

Formation of Mycelia.—Thirty hours after hanging-drop cultures were made with bouillon for nutriment the cell started out small processes (Fig. 7). In the next twenty hours they grew sixty microns in length. The mycelia were homogeneous and possessed a very thin cell wall. Where the media was adequate, its growth seemed unlimited; but where there was but little media they grew slowly and developed a firmer wall. Protoplasmic granules and pinkish vacuoles formed in the processes. Soon these granules became smaller and more dense. Then they manifested a very active brownian movement. After the mycelia were several days old, there appeared a subdivision of the mycelia into cells or segments of varying length (ten to one hundred microns).

These segments near the focus of growth continued to develop, assuming a spherical form.

After a hanging-drop culture in glycerin bouillon had developed for about a month there appeared an end cell that budded. In a few days there were four cells. These, as in several other places, developed until there were a dozen or more in a cluster.

Fortunately, one hanging-drop culture had but six microörganisms present, thus giving excellent opportunity to observe them individually. One of the budding forms started a mycelium. The process originated from a point near the attachment of the daughter cell. Shortly after the mycelia divide into segments, many of them sending out processes (Fig. 8). There were no more than one process from a given segment. The granules that formed in the mycelia showed a more marked brownian movement than particles in the surrounding fluid. It was as marked as the motility of the pigment in the malarial parasite. This movement lasted for more than two months. It was observed also in the mother cell. As the plant became older there appeared an extra development of some of the individual cells in the thread.

Fig. 8.—Blastomycetes. Dividing cell after ten days' growth in hanging-drop culture.

They took on a spherical form, and produced a protoplasm similar to the protoplasm of the cells in the teased specimen.

CULTURAL CHARACTERISTICS.

Petri Dish.—Six to nine days elapsed after a culture was made before any macroscopic signs of development appeared. Then a white area composed of radiating threads might be seen about the center of growth. If the cultures are observed with a microscope, these threads may be seen a few days earlier. One or more mycelia may be seen growing from a point as early as the third day. These soon subdivide, others are given off nearer its point of origin; these grow out in radiating lines, subdividing as they grow. The growth may be very rapid, the mycelia increasing two millimeters in length in a day. The rapidity of the growth did not seem to depend on the temperature so much as it did on the amount of moisture in the atmosphere. The most rapid growth was manifested when the Petri dishes were kept so there was considerable moisture condensed on the inner surface of the covers. In the Petri dish the most rapid growth was manifested in gelatin. It is interesting to note that in all media for some days no aërial hyphæ were produced. Instead, the growth spread beneath the surface in all directions. Later, however, the white aërial hyphæ appeared near the center of the growth.

Bouillon Culture.—Blastomycetes developed in plain, saccharin, glucose, lactose and glycerin bouillon. It is the most rapid and luxuriant in the glycerin bouillon. It grows most readily and rapidly on the surface and clings to the side of the tube very closely. It forms a mycelial growth on the surface of the bouillon so firm that it will prevent the bouillon flowing when the tube is inverted. If the tube is shaken a little after the growth develops, it is forced away from its position on the side and has the appearance of cotton. It never has developed the powder-puff appearance in bouillon. It is quite perfect in agar-agar, however. The teased membrane from the surface of the bouillon showed numerous conidia, three to six microns in diameter. There were also large conidia invariably filled with spore-like bodies. A little pressure between cover slips would liberate the contents of these bodies. Then all the appearances of the cells from teased tissues were observed. These large forms varied in size from seven to fifteen microns. Their arrangement in the teased materials suggested that they grew individually rather than in clusters of conidia.

Agar-Agar.—As has been mentioned, the early growth is quite completely beneath the surface. The growth is silvery white and forms a powder-puff-appearing hemisphere. It sometimes remains entirely beneath the surface and does not wrinkle. Again, it may wrinkle the surface. Sometimes eminences are thus formed from which beard-like tufts of aërial hyphæ are given off. As the culture advances in age it becomes slightly brown. The illustration will show the forms of growth as they appeared under the microscope. Conidia filled with spore-like bodies were also observed. The hyphæ varied much in diameter. There were some very fine forms measuring less than one micron.

Gelatin.—The gelatin plate grew very rapidly and did not wrinkle. No liquefaction was observed. The stab culture grew most rapidly at the surface. No liquefaction was observed in stab culture until after a month, when it was noted that the entire gelatin had gradually liquefied. At the end of three months it is perfectly fluid.

Litmus Milk.—The growth is rapid and abundant. The media changed to a deeper blue.

Potato.—The growth was as rapid as on plain agar. It was white and appeared like froth as the potato dried.

Loeffler's Blood Serum.—The growth was abundant, and did not seem to be more rapid than on glycerin agar. The color was not any different than what might be imparted by the media. There was no liquefaction.

Motility.—The motility of the protoplasmic granules was observed, but there was no motility of the entire microörganism.

Oxygen Requirements.—The cultures grown anaërobically by the Novy method showed no signs of growth in a month; but when removed from the hydrogen developed growth in seven days. A microscopic examination of material from the surface of the culture when taken from the jar showed no growth and no unusual forms.

Gas.—Although growth took place quite readily in the fermentation tube, no gas was produced, though grown in lactose, glucose and saccharose media.

By-Products.—No alcohol was developed in bouillon above mentioned. No carbon dioxid was produced in

quantities that could be detected. There was no nitrite or indol produced.

Destruction by Heat.—Growths in which there were aërial hyphæ grew readily after being exposed to 100 degrees C. for five minutes; while, if the hyphæ were submerged in bouillon before submitting to the heat, they were destroyed in less than five minutes at 54 degrees, centigrade.

Destruction by Antiseptics.—The microörganism is destroyed when exposed as follows: Five per cent. carbolic acid, for one minute; 2 per cent. commercial formalin, one minute; 1/1,000 bichlorid, for one minute. When exposed to 2 per cent. hydrochloric acid, specific gravity 1,320, for fifteen minutes, it not only was not destroyed, but it seemed to grow more rapidly.

Animal Experiments.—Of five guinea-pigs that were successfully inoculated, four developed ulcers at the point of inoculation. One developed simply a nodule. The ulcers were oblong, having the long axis parallel with the long axis of the body. In the center of a typical ulcer there is a dry, bloody scab. If this is raised it bleeds readily, while there may also be seen many pin-head-size gray foci. They suggest the miliary pustules characteristic of the human skin lesion. Around the central portion is a raised slightly indurated area from which the hair has fallen. The third day after inoculation one animal developed a subcutaneous abscess from which a bloody fluid was evacuated in which blastomycetes were observed. Two weeks after inoculation a ridge was noticed from the ulcer along the sternum to the clavicle, suggesting an enlarged lymphatic. The animals died a month after inoculation, all within a few days of each other. Although an epidemic was suspected it could not be proven bacteriologically, as blastomycetes were found near the seat of inoculation, while from the liver and spleen a pure culture of blastomycetes was grown in one instance. Cultures taken from the internal organs of the other animals did not develop any growth. However, had a larger number of cultures been made undoubtedly a positive result would have been more often obtained, for two-thirds of the successful cultures in the one case were negative. The lesions observed were numerous. Infarcts appeared in the lungs, kidneys, spleen, and in one case seven small, round hemorrhagic infarcts were observed in the stomach wall. Pin-point foci were seen in the liver and spleen. An ulcer was noted in the upper intestine. There was also quite an inflammatory condition in the axilla and groin, but no general glandular enlargement could be seen. One guinea-pig inoculated with material from agar-agar died in two months and manifested similar lesions to the above. Two rabbits were inoculated with teased tissue. Both lost in flesh, one more rapidly than the other. One is living; the other was killed five months later. No lesions were observed except numerous subcapsular scars in the kidneys. The microscopic study proved that they were a healing infarct. Two mice were inoculated with a culture after four months of artificial cultivation. They are alive after three weeks.

The microscopic study of the organs of the animals unfortunately has not been completed; nevertheless, quite a complete study was made of those of the guinea-pig dying of systemic infection. The same kind of lesions were noted as in the human. One observation is especially worthy of mention, namely, many large cells, apparently sporulating forms, as mentioned by Gilchrist,[12] were observed in the kidney sections.

There has also been a case of accidental infection following this case. The microörganism has been isolated in pure culture. It has also been observed in sections.

Experiments were undertaken to determine the effect of the *x*-ray on cultures of blastomycetes. They were exposed in Petri dishes with covers of oiled paper for periods from ten to thirty minutes in length every third day for two weeks. No visible effect was produced.

An ordinary sixteen-plate static machine was used with an *x*-ray tube of low tension. The distance of the tube from the cultures was two inches.

Cultures prepared in a similar manner were exposed to the influence of the light of an actinic ray apparatus. In these specimens, the growth of the organisms entirely ceased. However, a certain amount of heat was developed in the exposures, and it is impossible to determine whether the effect was due to the heat or to the influence of the actinic ray.

During these experiments, a very interesting observation was made. The paper covers of the Petri dishes were oiled, some with paraffin, others with cedar oil, to make them more transparent. In the case of those which were exposed to the *x*-ray, those cultures which were under the paraffin paper grew with their usual activity, while the growth of those under paper prepared with cedar oil was absolutely inhibited, and by culture experiments from those plates it was determined that the life of the parasites was destroyed. In a later experiment in which cultures were employed which had been growing for nine days, and in which the colonies had reached a considerable size, their further growth was entirely prevented by the cedar oil paper, while they continued to develop at a rapid rate in the control plate. In this case the cultures were exposed simply to the influence of the cedar oil, no other agents being used which might effect their growth. Subcultures from these plates made after an exposure of seven days to the effect of the cedar oil paper showed that the organisms were not yet destroyed, although absolutely inhibited. This observation may possibly prove to be of some value in the treatment of blastomycetic infections.

SUMMARY.

1. This case is one of systemic blastomycetic infection and belongs to a class of which but a very few instances have been reported.

2. Parasites were demonstrated in the blood post-mortem and dissemination evidently took place through this medium.

3. The lymph glands are remarkably free from infection.

4. In the lesions the parasites were found in immense numbers, and the inflammatory reaction in the tissues were of a remarkably slight degree.

5. The leucocytes of the blood and certain tissue cells contained large quantities of round pigment granules.

6. Parasites grow in the tissue only by budding, the forms appearing from five to fifteen microns in diameter; in artificial culture by segmented mycelia, lateral conidia, and in very old cultures a few budding forms.

7. There is a definite order of development of the parasite in the tissue, the younger forms having a densely staining protoplasm undergoing active cell division by gemmation; the older forms not deeply staining and not actively dividing, and containing spore-like bodies.

8. From the findings in the tissue it seems evident that sporulation occurs, five to fifteen spores developing in each cell where they are seen.

9. Organisms derived from teased tissues have been observed in hanging drop to produce mycelia within a few hours after they were removed from the tissue.

10. The effect of exposure to the *x*-rays was negative.

11. The effect of the actinic ray is doubtful because the element of heat was not eliminated.

12. The cultures covered with cedar oil paper died within one month. Those exposed for one week were completely inhibited from growth, but were not dead.

13. The organism fulfills the laws of Koch, guinea-pigs being more susceptible than rabbits.

14. The organism grows readily on all forms of artificial media used.

15. In gelatin liquefaction was produced after one month.

ANOPHTHALMOS.

REPORT OF A CASE.*

LAWRENCE R. RYAN, M.S., M.D.
GALESBURG, ILL.

The case of anophthalmos which I am about to report is not detailed for the purpose of deriving great clinical benefit from its consideration, but purely on account of its scientific bearing, and the possibility of throwing some light on the intrauterine disturbances that may cause the development of monstrosities.

Cases of anophthalmos are indeed rare, and cases of pseudoanophthalmos or microophthalmos are seldom enough seen to warrant us in presenting them to this scientific body. Aside from the complete absence of the eyeballs, other congenital deformities associated in this case are worthy of consideration. Then, too, the possibility of the influence of consanguinity in their causation makes it doubly interesting.

This case was brought to my knowledge in the following manner:

Sept. 7, 1894, I was summoned to a neighboring town to see a child about two months of age, which apparently had something wrong with its eyes. At a casual glance it seemed to be asleep, and aside from a tendency to anemia appeared to be fairly well nourished. On a more careful examination, however, anomalous conditions were brought to view. When I opened the lids I was astonished to find that there was not the faintest resemblance to an eyeball in either socket. The lids, palpebral muscles and orbits were perfectly formed. The lids were depressed exactly as in a case of enucleation of the eyeballs. The palpebral conjunction extended backward and made a complete sac. The most careful examination could not reveal anything that would indicate the presence of an eyeball, either large or small, nor did it appear that any retinal fibers had developed. I examined the child on several occasions during a year, but was unable to get any response to light stimulation. She slept during the day, but remained awake all night. This circumstance, however, is not uncommon with healthy children who have normal eyes. This girl lived until she was 3 years old and then died from enterocolitis. It was impossible to secure an autopsy. Therefore, any minute details or microscopic pathology can not be given.

There are those in the profession (and among them Fuchs) who deny *in toto* the possibility of an absolute anophthalmos, because in several cases eyes as small as a millet seed have been discovered by postmortem examination where anophthalmos was supposed to have existed. Of course, in this case in the absence of postmortem evidences we can not absolutely and conclusively prove our case. But from rational reasoning such an occurrence would seem possible. We have congenital deformities of all parts of the body, and there is no reason why failure in the development of the primitive ocular vesicle should not occur from some interference of nutrition. A few years ago the reports of the Royal London Ophthalmological Hospital gave ten cases.

During the course of the examination of this girl I found that she was deformed in various ways. The right external ear was smaller than the left. The meatus and internal ear were normally developed on each side. The hearing was abnormally acute, as is usually the case with the blind. Before she was a year old she could hear and recognize her father's footsteps long before any one else in the house, and would manifest her delight by clapping her hands.

The hands were flexed on the forearm at birth and the little and ring fingers of both hands were webbed as far as the second joint. By daily massage, however, the flexor tendons were relaxed and the hands and fingers could be fully extended and used normally.

At the lower third of both legs the bones were deformed and jogged, and large exostoses thrown out the same as in a case of fracture that had not been set. The tibia and fibula were involved alike. There was evidently an attempt at intrauterine amputation or arrested development of the extremities. At the time of examination, however, the bones were fully united and firm. Both feet were abnormally small. There were but four toes on each foot, and all the toes were webbed. In addition to this, both feet were inverted. There was marked varus, or equinovarus. Aside from these described deformities the child seemed normally developed. Mentally she was very precocious.

When such a train of congenital deformities occurs in the same child the profession as well as the laity are apt to attempt a solution of the difficulty. By the laity the condition is ascribed to one of two possible occurrences, namely, that the mother was scared by some animal or thing (in which event the child resembles the object that scared the mother), or it was produced by the near relationship of the parents. In this case the opinion of the laity may be set aside as far as the question of fright is concerned, for the mother had no remembrance of any such occurrence, and beside, the child bore no resemblance to a monster. On the other hand, however, the question of consanguinity enters largely into the case. The father and mother were first cousins. For those who recognize the possibility of deformities occurring in children whose parents are closely related, it opens a wide field for discussion and speculation. For my part I could never trace any physiologic or pathologic connection between deformities and consanguinity.

If we consider closely the nature of the deformities in this case we can easily see that whatever the cause of the uterine disturbance it affected the different parts of the fetus at practically the same time—that is, between the sixth and eighth week of gestation. It is true that the primitive ocular vesicle makes its appearance at the third or fourth week, but at the eighth the lens capsule is just beginning to form and the eye is just in the active point of development. At almost the same time the extremities begin to develop. At the fourth week we have the projection of the upper and lower limbs, but at the eighth week the thigh and leg can be distinguished. Up to this period the fingers and toes are webbed. Thus we have the absence of the eyeballs, which develop before the eighth week, and the webbed condition of the fingers

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

and toes, which also occurs before the eighth week, to prove that there was one great systemic upheaval, as it were, which arrested the development of the fetus at these points. What it was I will not attempt to say, for I was unable to elicit any information from the parents on this point. It may have been due to some displacement of the fetus in the uterus, or some temporary interference with the fetal circulation. It must have been temporary, for the fetus developed to full time without any further difficulty. Of course, the effect of some shock to the mother can not be overlooked.

Now as to the effect of relationship in these cases: Personally, I do not believe that *per se* it can have any effect. Two perfect physiologic beings ought to develop perfect offspring, other things being equal. The shortness of time, however, would preclude the possibility of going into this part of the subject in detail.

It is a well-known fact that breeders of stock inbreed closely if they wish to develop some particular trait in the animals, and especially a good trait. This is done with the most excellent results. However, there are few animals that have not some very objectionable characteristics, and these run along the line of heredity. To obviate the necessity or possibility of these bad traits developing out of proportion to the good ones it becomes necessary to cross the breed. For instance, a certain breed of horses are excellent trotters and also always produce good trotters, but they have bad tempers and become unmanageable. By too close inbreeding the vicious temper may more than keep pace with the development of speed, so the breed has to be crossed to secure a milder-mannered horse, even at the expense of a little speed. This condition will hold good among all classes of animals. A physiologically healthy man and woman, whatever the relationship, ought to produce healthy children.

The repugnance to consanguineous marriages is probably religious in origin, but has a basis of sound fact. People become diseased, and those who are closely related and dwell together are apt to develop the same diseases or defects of organization. The theory propounded above will also hold good here. Inbreeding among diseased or deformed humans will develop these deformities. For this reason it is a wise religious or political law that prevents it. It is a noteworthy fact that there are many degenerates and imbeciles among the royal families of the old country. This does not come, however, from the actual fact of relationship, but from the fact that syphilis, insanity and other diseases have been transmitted and developed at the expense of good traits. In many cases, however, remarkable genius has been developed in the same manner. The objection to marriage among blood relations has become so firmly fixed in the general mind that its influence may be felt. I can readily see that if a couple married who were closely related and the possibility of deformed offspring as a consequence of this relationship were brought repeatedly to the mind of a prospective mother, it might have some influence on the development of the fetus. I think there are few men in the profession to-day who are willing to deny *in toto* the influence of the mind on the body, and particularly the influence of the mother's mind on her child in embryo.

Both parents of this child were healthy and free from deformities. The mother was a primipara and 35 years of age. She was inclined to be anemic. The father was a large, rugged man, 55 years of age, unusually well preserved for his age. There was no specific history.

DISCUSSION.

Dr. Casey A. Wood, Chicago—Was the article referred to published in the Reports of the Royal London Ophthalmic Hospital by Lang in 1890? (Dr. Ryan answered "Yes.") I had something to do with the preparation of that article, and I thoroughly agree with Manz, who first made the statement that there is no such thing as a true anophthalmus. The primary optic vesicle forms so early that traces of it are almost always present, even if nothing can be seen or felt in the bottom of the orbit. In all the cases of anophthalmus so far reported which have been thoroughly worked out histologically some part of an eyeball has been found. I remember an alleged case of total anophthalmus, an account of which was published some years ago, in which it was stated, as conclusive evidence of anophthalmus, that nothing could be found at the bottom of the orbit by sight or touch. Of course, the primary vesicle does not constitute a developed eyeball, and in that sense the word anophthalmus might be a proper term to use for these cases.

Dr. J. M. Ball, St. Louis—In a case I have reported the child lived six months; the lids were perfect and there was a complete conjunctival sac. The appearance within the orbit was as if an enucleation had been done. The lachrymal glands were large and secretion was present. The whole subject has been worked out by Von Hippel and can be found in his contribution on the congenital anomalies of the eyes (Graefe-Saemisch Handbuch der gesammten Augenheilkunde). He has collected data in regard to the condition comprising 64 cases of double and 23 of unilateral anophthalmus. Most of them have been cases where postmortem examination was not permitted. Dr. Wood is correct in saying that in an ophthalmologic sense true anophthalmus does not exist, but clinically it occurs.

Dr. J. H. Claiborne, Jr., New York—Two years ago in New London I reported a case of double anophthalmus in which I reviewed the literature, and am much indebted for my knowledge to Von Hippel. I think Dr. Wood is correct, and yet we must have a name for the condition. If we separate the lids and find nothing we can surely say that it is a condition of anophthalmus. Double anophthalmus is more rare than single, and where it is double, as in the paper reported to-day, I think it should be studied with a great deal of care. The relation of the parents to each other is to be looked into. My case was the child of German parents, the father being much older than the mother. The child had no eyes; I could see to the bottom of the sacs. There was an imperforate nostril on one side and on one side the ear was lacking entirely, but there was an attempt at an external auditory meatus below. The father denied syphilis. I noticed one unusual sign, namely, a very high vault to the pharynx which was arched almost to a crevice.

Dr. S. C. Ayers, Cincinnati—I saw a case of so-called double anophthalmus a few years ago. The baby was several months old and, so far as I can remember, well formed. Between the lids nothing was visible except the smooth mucous membrane, just as though an enucleation had been done. I have in my neighborhood a young man with single right anophthalmus, the left eye being normal.

Dr. L. R. Ryan, Galesburg, Ill.—I simply present the clinical case, as I did not have the pathologic evidence. I do not see, however, why we may not have an anophthalmus, just as we may have the absence of any other part.

Fire-escapes and Tuberculosis.—The suggestion recently made by Dr. Alfred Meyer of New York, to utilize the fire-escapes of tenement buildings for the outdoor treatment of consumption, is an excellent one. The tuberculous poor would thus have the benefit of fresh air without the expense of leaving their homes. While the air in the streets of tenement districts is not to be compared to that of the country, it is certainly far superior to that which the patient would be compelled to breathe in a small room of a tenement house. The objection that might be raised that the use of fire-escapes for such purposes would be dangerous in case of fire is not an important one, for in such an event the patient would be the first to escape.—*Med. Age.*

CALCAREOUS DEGENERATION OF CORNEAL CICATRICES.*

H. MOULTON, M.D.
FT. SMITH, ARK.

Aside from, or in, association with hyaline degeneration (colloid of Saemisch), deposits of lime salts are described as occurring in the cornea, sometimes superficially, as in the so-called "band-like opacities,"[1] sometimes as infiltrates of small particles,[2] and, again, as larger masses in the form of plates[3] in old cicatrices. It is the latter type to which these remarks refer. Such cases are comparatively rare and clinical reports of them are rarer still. Some text-books do not mention them at all. I have seen but two cases, both occurring within the same month. As they present some interesting clinical features, I report them:

Case 1.—Mr. J. T. W., age 52, a merchant of Indian Territory, referred by Dr. Miller, came Feb. 20, 1901. He had an adherent leucoma in each eye, which he stated originated in an attack of sore eyes in 1865. Until recently the vision of the left eye had been the best. Of late all near work had been given up because it was attended with pain, smarting and excessive secretion of tears in that eye.

The leucoma of the right eye covered the temporal half of the pupillary area of the cornea and involved the iris, but there was nothing unusual in its appearance.

The opacity of the left cornea, about 5 mm. in diameter, occupied the inferior nasal quadrant. In the center, where the iris was most intimately involved, appeared a dense chalky white area 2 mm. in diameter. Its surface was smooth and glistening and the probe failed to reveal any roughness. The eye was not red and its conjunctiva was healthy. There was a prominent pterygium.

Javal's instrument showed the right cornea quite irregular and the left cornea with 7 diopters of astigmatism with the rule.

Vision: R. E. 15/60 with +1.5=15/45; L. E. 15/100 with +1. S. ⊃ +3. cyl. axis 85=15/40.

The pupils dilated to atropin in a direction away from the adhesions, but as good vision was not possible after dilatation as before. As I did not wish to cut into an adherent leucoma without positive indications, and as the symptoms were mainly of asthenopia, I hoped the use of glasses would give relief. These I ordered. I also removed the pterygium at the patient's request, for he attributed his discomfort to its presence. For a short time there was relief and the patient could attend to his books and correspondence. But in three weeks he returned complaining as much as ever. In addition to the other symptoms there was now for the first time a feeling as of a foreign body in the eye. Yet there was no redness or secretion. Feeling sure now that the degenerated scar was the cause of irritation, under cocain I pushed a sharp instrument into the chalky white part of the opacity and encountered a gritty substance. It was covered by superficial scar tissue, which I cut away. The gritty substance in the form of a plate, the thickness of writing paper and like eggshell in appearance and feel, was dug out. It was 2 mm. in diameter, irregular in outline and corresponded to the dense white, sharply defined area before described, lying over and resting on the adherent iris fibers. A deep, undermined excavation was left with exposed blood vessels at its bottom. There was no reaction. Healing was prompt. Relief was perfect and lasting. V. with correction 15/30. The use of the eyes has been comfortable up to this time. Scar is smooth and appears like that of the other eye.

Case 2.—Mrs. B. F. M., age 26, of Magazine, Ark., sent by Dr. Powell, came March 2, 1901, on account of pain in the left eye. Her right eye was normal. Her left eye was diseased when she was 3 years old, and from that time there has been a white spot on the cornea. Only during the past two years had the eye been painful. The pain was in paroxysms, lasting from three days to a week, with quiet intervals of corresponding duration. The pain was described as not that of a foreign body, but neuralgic in type, somewhat relieved when in the dark. It often drove her to bed. The eye was markedly divergent and presented a large dense cicatrix in the inferior nasal quadrant of the cornea involving the underlying iris. Its center had a chalky white area similar to that described in the previous case. The eye was not red, but flushed readily on examination. The fundus was visible through the temporal half of the pupil, with a pale and somewhat cupped disc. Vision: fingers at 1 foot; tension was plus. The glaucomatous symptoms led me to perform iridectomy, without relief, however, of the paroxysms of pain. Two weeks later I cut into the scar and dug out a calcareous plate, 1 by 2 mm. in area, almost identical with that of the first case. Healing was normal and there has been no return of the pain.

In both of the cases I felt certain at the first examination that the chalky white areas were the seat of degeneration, probably calcareous. The reasons they were not removed at once were: First, neither the probe nor magnifying glass revealed any break in the smoothness of the organic tissue overlying them; second, the symptoms were not such as usually are caused by a superficial foreign body, being in one case those of asthenopia, in the other more like those of glaucoma; third, there was some fear of exciting undue reaction by digging into an adherent leucoma, for merely exploratory purposes.

Later, the deposits in one case became partially uncovered, and gave rise to foreign body symptoms, at once indicating the proper procedure. In the other case I cut into the cicatrix, though its surface was still smooth, because the patient demanded relief, even if at the expense of the loss of the eyeball. It is now clear that the symptoms in both cases were due to the irritating effect of the hard substances resting on iris fibers deep in the cicatrices. We may conclude, also, that all leucomata involving iris, presenting a chalky area sharply outlined in contrast with the rest of the opacity, may be safely, and should be, cut into, even though the surface seems smooth. Are such deposits, *en masse*, found alone in adherent leucomata and not in those not involving the iris? That the masses removed were calcareous I take for granted from the statements of the books, but I regret that no microscopic or chemical tests were made.

PRESENT STATUS OF THE PURIFICATION OF PUBLIC WATER SUPPLIES.*

GEORGE W. FULLER.
Sanitary Engineer.
NEW YORK CITY.

Ten years have elapsed since the beginning in this country of the epoch of practical accomplishments in the field of municipal water purification. To record and review briefly the more important advances that have been made during the past decade, and to indicate the results, conditions and tendencies as they stand today, is the object of this paper.

In 1893 the water filter for the city of Lawrence, Mass., was put in service. Up to that date comparatively little had been done in the way of purifying city

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. S. Fulton, Seneca Egbert and H. M. Bracken.

water supplies in America; although it is to be remembered that in the early 70's several small sand filter plants were installed, notably at Poughkeepsie and Hudson, N. Y. They were built according to the plans of the late Mr. Kirkwood, following his investigations concerning sand filtration as then practiced in Europe.

Ten years ago mechanical filters attracted but little attention and were not looked on with favor by sanitarians and engineers. They were comparatively crude affairs in those days, representing but few of the improvements resulting from the transitional stages through which they have passed from their original form of mill or industrial filters to the types in which they are found to-day.

Prior to the construction of the Lawrence filter, the combined area of all filter plants then in existence in this country was not more than 1.5 acres, having a rated capacity of 4,000,000 gallons daily. The combined area of all mechanical filters at that time was about 12,000 square feet, having a rated capacity of about 35,000,000 gallons daily.

To those who have not followed closely the developments in this field of sanitary science it is almost inconceivable to look back and realize what uncertainty and differences of opinion prevailed concerning filtration as late as 1892. For some time prior thereto the medical and engineering journals of Europe had much to say concerning the outbreak of typhoid fever during the winter of 1889 in the eastern portion of the city of Berlin, where water consumers were supplied with filtered water from the old Stralau sand filters. At London a royal commission was engaged in an investigation of the future supply for the metropolitan district, and received testimony from many prominent sanitarians to the effect that, in their opinion, filtered Thames river water should be abandoned, and that new supplies should be obtained from mountain sources. In a number of European cities discussions were taking place as to improved water supplies, and many sanitarians urged that new supplies should be drawn only from pure mountain streams, or from ground water.

In view of the somewhat conflicting evidence at that time as to the merits of water filtration, there was conducted at the Lawrence experiment station, as is well known, a series of experiments, starting in with the use of very fine materials, including loam, and very low rates of filtration, giving conditions not much unlike those which had been studied shortly before at that place in connection with sewage purification. In this way evidence was gradually accumulated from tests made under various conditions as to coarseness of materials and rates of filtration, which led, in 1892, to the conclusion by the Massachusetts State Board of Health that the purification of waters as highly polluted with sewage as that of the Merrimac river could be successfully accomplished at a reasonable cost.

Opportunities for putting into practice the results of these investigations, and in the city where they were developed, came quickly. The several large cities in the valley in which Lawrence is situated, and including Lawrence itself, had suffered severely for a number of years from epidemics of typhoid fever due to sewage pollution in the Merrimac river, from which they obtained their public water supply. In the late summer of 1892 it will be recalled that Asiatic cholera appeared in New York harbor. It was the appreciation on the part of the Lawrence city government of the calamity that would befall them, should cholera become established temporarily in the cities situated on the Merrimac river above them, that caused them to take the initial step paving the way for an era of practical accomplishments in municipal water filtration. They placed at the disposal of the water board such sums of money as were available from their limited funds, and construction work was commenced. The Lawrence city filter was carried to successful completion under the guidance of Mr. H. F. Mills, engineer member of the Massachusetts State Board of Health and put in service in September, 1893.

Immediately following developments at Lawrence, Mass., came the first of quite an extended series of investigations as to the efficiency of different styles of filters, and under widely different conditions. The first investigations were made at Providence, R. I., under the charge of Mr. E. B. Weston, engineer of the water department there, and were directed especially to the efficiency of mechanical filters in purifying the Pawtuxet river water. This water is not muddy, but contains considerable vegetable stain and at times is subject to more or less sewage pollution. The Providence tests, which were made on a small scale, led to the conclusion, reached for the first time on data covering a considerable period of time, that mechanical filtration under reasonably favorable conditions would give efficient purification.

Following the Providence tests, a series of three investigations, namely, at Louisville, Pittsburg and Cincinnati, was made, showing the results which could be expected on a large scale in treating certain of the muddy waters of the South and West. The results of each of these investigations were made public in detailed reports during the years 1898-99.

As is well known, surface waters of the South and West ordinarily contain so very much more mud than do the waters of New England and most of the European rivers, where large filter plants have been established, that officials in charge of waterworks plants in the South and West were in former years exceedingly skeptical as to the practicability of filtration, not only on the ground of cost, but also of efficiency. The three investigations mentioned, covering a period of four years, and representing an expenditure of upward of $200,000, furnished information sufficient to place the subject of purification of ordinary muddy waters on a reasonably satisfactory basis.

Without going too much in detail into results of the investigations in question, it may be said briefly that they showed the limitations of sand filters in the treatment of muddy waters; the urgent necessity of preparing very muddy waters for filtration by the removal of mud by means of settling reservoirs and by coagulation prior to filtration by any method; the probable limitation to which plain subsidence could be advantageously carried with the types of water in question; the best available means of coagulation; and the suitability of filters, both of mechanical and sand bed types, in treating these muddy waters after the removal therefrom of excessive quantities of mud.

Following the investigations made on the Allegheny and Ohio rivers there were several other investigations, among which are those made in Washington, Philadelphia, New Orleans and Harrisburg. The Washington investigations have been published in detail, and were largely confirmatory of the results obtained at earlier dates. Those made at Philadelphia and Harrisburg have not yet been published in detail. At New Orleans there is just issuing from the press a detailed account of the investigations made under the direction of Mr. Geo. G.

Earl, who has described to you the general conditions in this city regarding the installation of a new system of sanitary works, including an improved water supply.

These investigations at New Orleans were conducted for about one year, beginning in the autumn of 1900, and were under the immediate charge of Mr. R. S. Weston. A brief summary of the results of these investigations is next given.

To appreciate the conditions of water purification of the Mississippi river at New Orleans it is necessary to bear in mind that the drainage area of this river comprises about 1,240,000 square miles, extending from the Canada line to the Gulf of Mexico, and from the Appalachian to the Rocky Mountains, the aggregate area representing more than one-half of this country. On this area is an urban population of over nine million people resident in towns having a population of more than 4,000.

Regarding the physical condition of the Mississippi river water at New Orleans, it may be said that it is turbid at all times. Records of the amount of suspended matter are available for seventeen complete years, fifteen of which are based on results of observations made by the Mississippi River Commission. The average amount of suspended matter as compared with that in waters elsewhere is shown by the following table:

		Suspended Matter.	
		Parts per mil.	Tons per mil.
City.	River.	River Water.	Gallons.
Lawrence	Merrimac	10	0.042
Albany	Hudson	15	0.062
Pittsburg	Allegheny	50	0.208
Washington	Potomac	80	0.333
Cincinnati	Ohio	230	0.957
Louisville	Ohio	350	1.480
New Orleans	Mississippi	650	2.70
St. Louis	Mississippi	1,000	4.16

While it is seen from the above table that the total amount of mud in the Mississippi water here is less than at St. Louis, it is a fact that the water at New Orleans contains a far greater proportion of submicroscopic clay particles. At St. Louis from 80 per cent. to 90 per cent. of the mud is so coarse that on an average it is deposited in settling basins holding twenty-four hours' flow. At New Orleans a basin of similar size would show a deposit of only about 45 per cent. of suspended matter, leaving in the settled water about three times as much very fine clay as would be the case in the settled water from below the mouth of the Missouri river.

The difficulty in treating the New Orleans water from the Mississippi river is apparent when it is stated that purification works for this city must remove on an average each day some fifty to sixty tons of submicroscopic clay particles, nearly all of which are smaller than bacteria, and many of which are not more than one-tenth the size of the latter. This is the most difficult feature to be contended with in the local purification works, as it can be stated that with the removal of the clay particles on a satisfactory basis the bacteria will take care of themselves, because, owing to their size, their removal is generally easier than are the last traces of these clay particles.

Another factor in this connection is that the hygienic condition of the raw Mississippi river water at New Orleans is better than one might suppose at first thought, after reflecting on the large population which drains into this river. As a result of more than 100 examinations of the water in volumes varying from one to three hundred cubic centimeters, the presence of the colon bacillus, the leading microörganism of the intestines, was detected only in three instances. These conditions are not so surprising when one stops to consider carefully that there are only about 45,000 people resident in cities which discharge all or part of their sewage into the Mississippi river within 600 miles of New Orleans and none within 130 miles. The remaining population of the Mississippi delta does not drain into the Mississippi, as the slope of the ground is away from the river.

Stating briefly the results of the New Orleans investigations, it may be said, first, that plain sedimentation for a period of three days, followed by slow filtration through sand beds, according to European practice, proved to be impracticable, because of excessive cost of cleaning the beds, and also of the fact that for many months at a time the filtered water would contain so much clay that it would be unsatisfactory for municipal use. Indeed, it may be said that if all the money available for the construction of the new system of waterworks in this city, including pumping stations and distributing pipes, were expended in the construction of settling reservoirs they could not sufficiently clarify the river water in order to prepare it adequately for filtration.

A procedure which was found to be successful is that involving the use of a coagulant to mass together the tiny clay particles into bunches of sufficient size so that they can be handled efficiently by sedimentation. Water so treated was studied in connection with both types of filter; that is, sand beds and mechanical filters.

One of the most important features studied in New Orleans was the economical and advantageous limits to which plain sedimentation could be carried; that is to say, the most practical division of work under local conditions between plain subsidence and coagulation followed by supplemental subsidence; and, further, the degree of clarification which it is advisable to provide for the water prior to its application to the filters. It was found that where sand beds are used the best arrangement consists of a plain settling basin holding twelve hours' flow on an average, followed by coagulating basins holding twenty-four hours' flow, from which the treated water, containing about thirty parts per million of clay would pass through sand beds at a rate of about 5,000,000 gallons per acre daily, or double the German standard rate. Where water is applied to mechanical filters, the best method consists of plain settling basins holding twelve hours flow on an average, followed by coagulating basins holding another twelve hours' flow, thus bringing the turbidity of the water as low as fifty to seventy-five parts per million, and so that it could be satisfactorily treated by mechanical filters at rates of from two to three gallons per square foot of filtering surface per minute.

Comparing the relative merits of these two types or systems of water purification it is found that the one involving the use of mechanical filters would be about $500,000 cheaper than the one involving sand beds; that the former would also be distinctly cheaper in total cost, involving both fixed charges and operating expenses; and that it would give a quality of water as to both clearness and hygienic conditions equal to that furnished by the other type of filter. Hence it was concluded to recommend the adoption of the so-called American system, involving the use of plain subsidence, coagulation and mechanical filters.

Regarding the question of coagulation, the New Orleans investigations were made with the use of sulphate of alumina, which it is proposed to use in practice unless it is found that a more advantageous chemical should

become available. In this connection it may be stated that the Mississippi river water always contains an adequate quantity of carbonates of lime and magnesia in order to decompose the coagulating chemical so that with a reasonable grade of supervision there is no likelihood whatsoever of undecomposed chemical entering the filtered water.

Another feature to be mentioned in this connection is the fact that the Mississippi river water does not vary with extreme rapidity in its composition, and hence the application of coagulant solution would be on a much more regular and uniform basis than in many places where the process has been considered.

It is possible to use compounds of iron for purposes of coagulation of waters like that of the Mississippi, but at the present time there is no information to indicate that they would be better or cheaper than sulphate of alumina. In the course of the Louisville investigations much study was given to the practicability of coagulating waters by electrolytic treatment in which there is obtained the hydrate of the metal used, that is, of iron or aluminum. These hydrates mass together the clay, bacteria and other particles suspended in the water in a manner similar to that effected by means of aluminum hydrate formed from the decomposition of sulphate of alumina. This electrolytic process, as the evidence now stands, is not only more expensive, but can be controlled much less readily than in the case of sulphate of alumina. Electrolytic processes, if they could be utilized in a practicable manner, would have two advantages: One is that they do not convert lime and magnesia from carbonate to sulphate, the latter of which is less desirable in water used for steam-raising purposes. The second is that such processes would overcome sentimental objections which appear to prevail in some communities against the use of sulphate of alumina in water purification. It is not definitely proven that some electrolytic process may not some day assume practical form, but there is no evidence now available to indicate such an outcome.

As to the question of the use of sulphate of alumina in water purification, the present feeling in this branch of municipal work is that it is not judicious to use it if equally efficient results can be accomplished at equal cost without it. There is, however, no evidence on record to indicate that harmful results follow its intelligent use, as is testified to by the actual experience of over 200 cities and towns in this country, with an aggregate population of about 2,000,000 persons.

The New Orleans investigations are undoubtedly entitled to a prominent place in the history of water purification, in that they show conclusively that works can be constructed successfully to clarify and purify waters charged to the highest known limits with submicroscopic clay particles, and at reasonable cost, coming within the financial limits of the average municipality.

Referring to developments in the general field of water purification, it may be said that recent practice points clearly to the advantage of much more thorough preparatory treatment of waters prior to filtration than was formerly the case, and to the use of higher rates of filtration than were previously considered advisable. This applies not only to the rapid method of the mechanical type of filter, but also to the sand bed type. In connection with the latter the use of preliminary or roughing filters has unquestionably much merit in the treatment of certain types of water, as shown by developments at Philadelphia and at Zurich. The future will undoubtedly show still further advancement in the successful use of double filtration, not only in the case of certain turbid waters, but also of waters highly polluted with sewage.

The use of ozone has received attention for many years in connection with water purification, especially concerning the endeavor absolutely to sterilize water as it is supplied to the consumer. Whether or not this is necessary or even desirable is very doubtful according to present evidence, and it is not likely that it will become a prominent feature in large municipal works for some time to come, owing to the cost of producing ozone or ozonized air in sufficiently concentrated form to effect sterilization. This is due partly to the expense of electric generating devices, and partly to the fact that ozone treatment, according to present indications, can be regarded only as a supplemental step following filtration, and not a substitute therefor. The reason why the application of ozone has to follow filtration is that it is essential first to remove the organic matter as far as possible from the water, thus reducing the quantity of the ozone required for sterilization purposes, to say nothing about needs for clarification.

Such application of ozone would prevent or destroy those growths of bacteria which, as well known, occur to a greater or less extent in the underdrains of sand filters, and occasionally in mechanical filters. As such growths refer without exception to harmless kinds of bacteria and not to disease-producing germs, there is no reason to believe that the cost for applying ozone for this purpose would be justifiable.

Regarding the treatment of surface waters stored in large ponds or reservoirs, and such as at times contain very objectionable odors or taste, investigations conducted at Springfield, Mass., in 1901, on the famous Ludlow Pond water indicate that it is practicable to make such waters satisfactory by double filtration through sand beds in conjunction with aëration.

As to the decolorization of swamp or marsh waters, experience has indicated that this can be accomplished by means of coagulating treatment, as is shown by the purification works in the city of Norfolk, Va. Without coagulant, such swamp or marsh waters can not be successfully freed from vegetable stain.

As a general proposition, it may be stated that in the light of present knowledge practically any water may be successfully purified by some combination of the various processes which have up to this time been studied with care, and at a cost ordinarily ranging from one-half to one and one-half cents per thousand gallons, depending much on local conditions.

In regard to the construction of purification works, material progress has been made in recent years, and many works recently designed are not only of a much more permanent and durable nature than in earlier designs, but they are especially improved as regards convenience and facility of operation. This particularly applies to mechanical filters, as is perhaps best shown by the plant recently put in operation at Little Falls, N. J., by the East Jersey Water Company. This plant, occupying about one acre in area and capable of producing 40,000,000 gallons of filtered water daily, is the largest completed plant in the country, although larger ones are in process of construction. The structures are entirely of concrete, and all devices, so far as practicable, are made automatic, or arranged to sound automatically a gong to call the attention of the operator to what is required. Hydraulic cylinders are attached to all valves and are operated by levers conveniently placed. Water and compressed air for washing the sand layers are

turned on and off by pressing a button, thus stopping and starting the motors operating the machinery.

Concerning sand filters, the improvements in design are not so striking, yet they are important, and should eliminate many of the complications encountered in the old-fashioned filters abroad where unsatisfactory results were occasionally obtained.

To gentlemen especially interested in the field of hygiene there is probably no question so important as that of the results accomplished by filtration in the reduction of water-borne disease among people using filtered water. In this connection the well-known experience with the Lawrence filter is very gratifying in that it has shown year after year, while in its normal operation, a typhoid fever death rate as low as that in the neighboring city of Lowell, which now derives its supply from pure underground sources. Similar experience has been gained at Albany since the completion of the very well-built sand filter at that place. As to mechanical filters very little experience has been gained with plants fully equipped with devices in accordance with the results of the investigations herein reviewed. The results of many thousands of analyses show that with both types of filters built and operated under favorable conditions there is practically no choice as to hygienic efficiency on an average. In winter mechanical filters are slightly superior, and in summer the reverse may be true.

At the beginning of the second decade of developments in this field it may be said that matters appear very bright indeed. The doubts and uncertainties of ten years ago have very largely disappeared. In Europe it has been learned that many of the former arguments against filtration were based on exceptional conditions caused by the arrangement of filters built fifty years ago. Progress there has been substantial, and we hear but little now of ground water or the mountain spring, except where such waters are obviously the most feasible. We have learned in this country that no such thing exists as a "cure-all," that is, a single type of purification works adapted to treat satisfactorily all types of waters; but we have also learned that purification works can be built to purify practically all types of water, and that satisfactory results can be predicted with confidence. That this confidence is shared by municipalities and citizens is shown by the great amount of construction work now going on and in early contemplation in this field, especially in the larger cities.

DISCUSSION.

Dr. G. T. Swarts, Providence, R. I.—The subject is one of the most important of those which come up for consideration before any health board, whether it be of a small township or of a large municipality. Sooner or later, almost every inland city is called on, through its health department, to make provision for a water supply of some sort, and the available sources are never what they should be. Filtration in a majority of cases, perhaps, will be required in order to put the water in good condition. This paper, dealing with the general drift of results, and giving a historical retrospect of all the different methods in a condensed form, makes it a valuable document, which will be eagerly read by sanitarians in general; and even those who are thoroughly familiar with all the details of the subject will be glad to find them given here in so condensed a shape.

It was very interesting to me personally, having visited the experimental plants in Louisville, Cincinnati and Pittsburg, to see the difference in the character of the waters and the facility, after a great deal of experimentation, with which these experts have handled a water which, as described by the previous paper, carries with it a material which makes a clay so fine that it admits of the introduction of a spade with facility, and yet is elevated with a good deal of difficulty. It is a matter that comes up here differently than it does in the northern cities. There is here a fine silt which it is difficult to dispose of, and which will quickly clog any known form of filter. It is a point of interest to us and to the layman, looking on the Mississippi River water, watching it as it flows into the tubs of the hotels, to think that the time will come when it will be possible to dispose of that silt and raw material, and to get a white, clear water, as pure as that of any artesian well in the country.

I am glad to hear Mr. Fuller emphasize the fact that the introduction of sulphate of aluminum is not such a bugbear as was thought in the matter of the introduction of mechanical filters. That is one of the greatest setbacks we have had in the north, where it was impossible to show the people the necessity or desirability of using a coagulant. Of course, it is not always necessary to do so; yet it is possible, as I understand it, to thus remove a greater amount of the color from waters which are discolored by decaying vegetable and animal matter, stumps, etc., than without a coagulant.

In the city of Providence, where we want to get fifteen to twenty million gallons of water per day, we endeavored to introduce the mechanical method, but failed in the effort from the simple fact that the city took a sentimental view of the matter, and also, unfortunately, of the attack made on it by physicians themselves, bringing up this objection to the sulphate of alum. They wanted the water filtered in the natural way, as Nature filters it, not stopping to think that the water from artesian wells has been exposed to all kinds of chemical changes for years. Their idea was that the water had to pass through sand, as that was Nature's method; and therefore sand filtration was adopted.

It was a surprise to me to learn from this paper (if I have correctly understood it) that the manipulation of the water supply of New Orleans would cost less if mechanical filters were used. Of course, that was a great pleasure to me, being interested in mechanical filters. Another point that struck me was the simplicity of the operation. It can be handled by fewer individuals. It is not dependent so much on detailed work, such as is necessary in sand filtration, where a large number of operatives are required, who may not be familiar with all the branches of the subject, and are liable to contaminate the beds while they are being scraped.

I would like to inquire, with reference to the possible or probable time within which this filtration can be established. I want to know this in order to be posted when I am quoting the grand advancement made in the water and sewerage system of New Orleans.

Mr. George G. Earl, New Orleans—Three and a half to four years.

Dr. W. C. Chapman, Toledo, Ohio—The advance in this science has been so great that the people have not been able to keep up with it. For several years I have been interested in the water supply of Toledo. I find great ignorance regarding filtration. One of our principal endeavors should be to enlighten the people on the subject.

Dr. Swarts speaks of coagulation by alum, which is strongly opposed by many in our cities because it is ignorantly supposed the chemical remains in the filtered water. We are about to take steps in Toledo to filter our river water, and we have had Messrs. Hazen and Benzenberg investigate as to the possibility of getting good water and from whence the supply should be taken. We have two sources of supply: the Maumee River and Lake Erie. The difficulty we have had to overcome is that many think Lake Erie water is pure; that it only has to be drawn into the houses by pipes. Investigation shows this is not true, and that to get good water filtration must be employed. Lake water is impure; the lake, being very shallow, is merely a large catch basin for the surrounding country.

We must instruct the people on the subject of water purification. We have overcome prejudice to a great degree in Toledo, so that a plant will be installed which will be large enough to supply water for 350,000 people. The water has

been tested by the State Board of Health. The state bacteriologist finds Maumee water can be purified so as to be potable and therefore healthful.

In my opinion, the mechanical filter is best for rivers with much sediment. Our river is different from the Mississippi. It becomes very muddy after a storm or a freeze and thaw, but it usually clears itself in from forty-eight hours to three days, and we then have clear water until after another storm. Subsidence takes place easily and therefore the necessary coagulant will be small in quantity.

Dr. E. B. Borland, Pittsburg, Pa.—We know from examinations made in the last two decades that almost any contaminated water can be purified to a reasonable degree. Mr. Fuller alluded to the real filtration material, of which I expected to hear more; I refer to the albuminous gelatinous material and bodies of bacteria which form the real filter medium. No doubt he took it for granted that we were all acquainted with it and therefore merely alluded to it. I find the public, the laity in general, have no idea of the principal or real factor in sand filtration; when the material which gathers on the upper layers of sand becomes too thick and dense the upper inch can be removed and cleaned. I don't recall that Mr. Fuller referred to the cleaning of the upper layer of the sand filter, but I have no doubt that he expected us to know and understand that such cleaning is necessary.

I have been considerably interested in the subject of sand filtration, though not as much so as in mechanical filtration. In our experiments in Pittsburg in 1897 and 1898 three mechanical filters were tested alongside of two sand filter beds. The summary of the bacteriologic test was as follows:

> The average bacterial efficiencies of filters on the respective systems, as developed by our tests, were an average of 99 per cent. for the sand filters, and from 97 to 98 per cent. for the mechanical filters. With the sand filters the efficiencies for the summer months and particularly those months when the number of bacteria in the raw water were highest, were very much above this average, reaching, during October, 1897, the remarkable efficiency of 99.96 per cent.

These experiments were carried on by the Pittsburg Filtration Commission, and an exhaustive report of 350 pages was made. The bacteriologist of the commission found as many as 57,000 bacteria to the cubic centimeter; and when there were 30,000 bacteria, 98 per cent, of them could be removed in the sand filters without a coagulant. The mechanical filters, as I have stated, with the coagulant made results of 2 per cent. less in efficiency, in the removal of suspended matter and bacteria.

Now, it has been said that the waters west and north have much less of this fine submicroscopic clayey material which Mr. Fuller and the gentleman who preceded him have emphasized. I can see why this factor demands attention in New Orleans and other cities in the south which are considering filtration. In Pittsburg, we have ordered the construction of sand filter beds, without the use of a coagulant, in accordance with the recommendation of the filtration commission.

Dr. Seneca Egbert, Philadelphia—I feel that this kind of work, represented by the papers we have heard to-day, is most highly educational, and that we ought to do all we can to disseminate such information. Much of the danger lies not in the cities but in what is being done in the country. There are many small towns whose water supplies can be very much improved by the adoption of modern methods of sewage disposal, as well as by improvements in the purification of the water. Almost every one of these communities would throw aside any suggestion of filtration, as being too expensive; but what we have to do, and the task that is specially incumbent on us, is to educate the profession throughout the country so they can make the local authorities realize that it is the highest economy possible to take these measures—not in ten years hence, but now—looking to the purification of the general water supply. Every town of five, six or eight thousand inhabitants ought to have clean water, and the cost is exceedingly small compared with the cost of sickness and mortality that result from typhoid fever and other diseases due to bad water. There is not a town in the country that could not improve its health status by attention to, and local application of, the teaching of just such papers as we have heard to-day.

Dr. F. J. Mayer, Lafayette, La.—So far as Louisiana is concerned, I can assure this body that from the Arkansas line to the Gulf the average drinking water is hardly fit for human consumption; the principal source of supply in the country districts is from rivers and branches, shallow wells and cisterns. The water from the last named source, when caught in seasoned cypress cisterns during the winter season, the spring and summer supply being shut off by automatic cut-offs, is really the most potable water we have. Outside of the Mississippi River, our river waters are not wholesome, though palatable. The Mississippi River is the largest body of potable water in the world, and wholesome and palatable when properly treated. The proof of this is that ship captains find that it keeps better in the tanks of their vessels when precipitated with an ordinary coagulant than any other water; and in antebellum days the creoles of this city kept Mississippi water in urn-shaped jars holding about fifty gallons. They in this way secured a very potable water supply by adding about 5 grains of alum to the gallon as a precipitant.

In our larger inland towns, like Monroe, which is supplied by the Ouachita and an artesian well, it is difficult to determine which is worse for drinking purposes. Some years ago, when the Ouachita was very low, I found that the intake pipe was within a few hundred feet of a private sewer that emptied into the river. A bacteriologic and chemical analysis of the two waters by Professor Metz, expressed in parts per one hundred thousand, exhibited 94,876 bacteria per cubic centimeter. On plating some of the cultures evidences of the presence of the *Bacilli coli communis* were found; also organic and volatile matter, 3.6000; nitrite 0.0040; nitrates. 0.0669; mineral matter, 8.4500; total solids at 240 F., 11.8000. The artesian water, though brackish and containing volatile and organic matter: 5.7000 parts, and 72.1000 parts mineral matter at 240 F. was the least dangerous, owing to the absence of nitrates and nitrites, and of the *B. coli communis*.

The shallow wells, which really constitute the largest supply to the farming population, are absolutely unpotable, in many cases reeking with microbian filth, sometimes sparkling with nitrates and nitrites, the result of animal decomposition; and yet the poor, deluded farmer imagines that he not only has a healthful water supply, but thinks it has medicinal properties on account of the gas sparkling in it, and on account of the odor resulting from decaying vegetable and animal matter, which he attributes to the presence of sulphur. There is no excuse for this, for at a depth of from 60 to 270 feet an abundance of potable water is to be found all over the state. So I think, as the last speaker said, it is absolutely requisite and necessary to educate the general public on these facts with which we are familiar, but of which they know nothing.

Dr. W. G. Owen, Whitecastle, La.—Dr. Mayer mentioned the fact that one of our chief sources of supply, all through the southern portion of the state, is cisterns, the water coming from the roofs of houses, bringing with it all the dust and dirt accumulated through a long drought. I have found this a very potent factor in the dissemination of typhoid fever. In fact, I have seen one instance where three or four members of the family were attacked with the disease, which continued to spread until they began to boil the water. That ended all extension of the fever.

Dr. E. B. Borland, Pittsburg, Pa.—In the experiments in Pittsburg, the mechanical filters were operated with a coagulant, and the sand filters without it. I have no prejudice against mechanical filters, notwithstanding that we have had political corruption, as have other communities. I think almost any Pittsburg citizen will say that ours was a representative commission. There were on it scientists as well as politicians, and men of a high degree of culture and integrity; and while we are inclined in Pittsburg, as elsewhere, to criticise public officials, it is the consensus of opinion that the commission was unbiased in its report recommending the

use of sand filters. I agree with the proposition that different treatment is required for different water supplies.

Mr. George W. Fuller, New York City—Replying to the discussion of Dr. Borland, in which he mentions the gelatinous materials around the sand grains, it is true that this is characteristic of sand filtration as ordinarily practiced with the waters of Europe and the northern portions of this country. Around the sand grains there are formed gelatinous films, and at the slow rate at which the water passes through the pores of the sand, the bacteria and other matters suspended in the raw water are detained by them until, in the instance of the bacteria, many of them die. Of course, a large number of bacteria are removed when the upper portion of this sand layer is removed by scraping. These scrapings are from time to time necessitated by the surface of the sand layer becoming clogged to such a degree that the regular volume of water can no longer pass through the sand layers.

With the waters of the south and central west the conditions are somewhat different, in that the organic matter capable of forming gelatinous films around sand grains in the sand filter is absorbed to a large degree by the sand, silt and clay in the water itself as it flows in the stream. Consequently, this material, so important in the behavior of the sand filter, is lacking for the performance of the work in filters where it is needed more than in the case of European waters.

Removal of the silt and clay in the muddy southern and central western waters by means of sedimentation in large basins, in order to allow filters to operate economically, of course, eliminates this organic matter still further; and the influence which it might produce on a sand layer if the water were applied directly is therefore lessened. Combining all of these influences and conditions, it is found that it is an essentially different proposition to clarify and purify successfully a water which is highly charged with silt and clay and lacking in organic matter, from what it is to purify a fairly clear water which is capable of supplying organic material capable of producing gelatinous films by natural means around the sand grains in a sand filter. This, perhaps, may make it somewhat clearer why it is that in certain waters it is so essential to produce artificially the gelatinous materials for the detention and removal of bacteria, and such as is provided by aluminum hydrate resulting from the decomposition of sulphate of ammonia.

As to the question of the mechanical filters during the Pittsburg tests having shown somewhat lower efficiency in the removal of bacteria than in the case of the sand filters, it is to be borne in mind that the degree of bacterial removal by mechanical filters is largely a function of the quantity of coagulant applied. Had there been applied during the Pittsburg tests a somewhat greater quantity of coagulant, there is no reason whatever to believe that the removal of bacteria by the bacterial filters would not have equaled that obtained from the sand filters. During the development of our practical knowledge of mechanical filtration during the past few years, there is no feature the importance of which has grown on us so much as the imperativeness of providing at all times an adequate quantity of coagulant. In the early days of mechanical filtration on a practical scale this was not done, and to-day this criticism can be made of many plants. It also may be said very frankly that occasionally throughout the elaborate tests conducted both at Pittsburg and Cincinnati, the quantities of coagulant were not sufficiently high to place mechanical filtration in its best light.

Different waters unquestionably require different methods of treatment. For some waters sand filters are best, and for others mechanical filters are best, in each instance making due allowance not only for equal efficiency from a hygienic standpoint, but also for cost of installation and operation.

To Remove Perspiration Odor.—A dram of formaldehyd to a pint of water sponged about the genitals and axilla will remove the odor of perspiration. A stronger solution will check excessive perspiration and fetor of the feet.—*Medical World.*

MEATOTOMY PLUS MEATORRHAPHY.

JOHN PRENTISS LORD, M.D.
Professor Surgery, Creighton Medical College; Attending Surgeon, St. Joseph's Hospital, and Consulting Surgeon, South Omaha Hospital.
OMAHA.

The incision of the urethral meatus in the male often becomes necessary to allow of the passage of urethral instruments, especially for sounds and catheters of large size, for urethroscopes and cystoscopes, the segregator, etc. In the days when meatotomy was required for the passage of sounds principally this operation seemed to satisfy. But now that the surgeon must wait until healing of a meatotomy wound takes place before proceeding with his refined methods of diagnosis, the slow process of healing by granulation and the necessary daily separation of these divided surfaces which lie in contact and which reunite immediately unless torn apart by force, is tedious, usually bloody, and daily inflicts an amount of pain poorly borne by the patient, and the result is apt to be imperfect for obvious reasons.

The writer recognized these objections several years ago and began suturing meati whenever a meatotomy was done. Four or five 00 catgut interrupted sutures were used. The hemorrhage, which may be rather free

Figure 1.

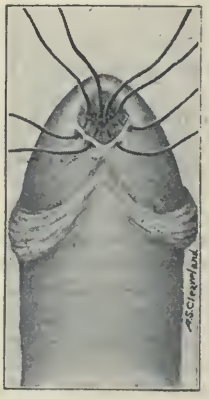

Figure 2.

Figure 3.

or even serious in some cases, is immediately arrested. Healing has always been primary. The case requires no after-care, the patient is saved much suffering, the surgeon unpleasant and unnecessary responsibility, and it is unnecessary to divide the tissues so deeply to get the same results. If it is done to enable the surgeon to use the cystoscope, this instrument can be used in a day or two without blood smearing the lamp, which would interfere with the examination.

Works on surgery describe the operation of meatotomy and recommend the daily introduction of a sound to prevent union of the apposed wound surfaces; and recent works on genito-urinary surgery follow in the same rut.

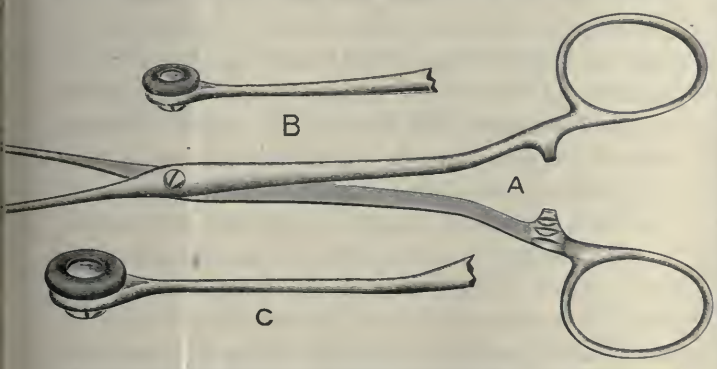
An extended search by the writer fails to disclose any suggestion of meatorrhaphy. A considerable inquiry among the writer's friends also fails to find any use or recommendation of this simple measure, and the writer is surprised that he is obliged at this writing to consider himself its author. It has been practiced by him for several years, and not until his curiosity was excited by failures to find it done by others has he deemed the matter of enough importance to present it to the profession. It is herewith presented as a small contribution to surgical advancement, and even though in prior use it is desirable that attention be directed to so simple and

valuable an operation, evidently now unused by the profession, which is ever ready to avail itself of even the slightest detail of surgical technic that will add aught to the sum total in the refinement of its art.

Since writing the above, a renewed search has disclosed the following in Tillmann's work on surgery: "Stenosis of the external meatus with a corresponding difficulty in urination is comparatively common. This can be easily remedied by incising the meatus toward the frenum and suturing the edges of the glands to the mucous membrane of the urethra. In the more marked cases one may dissect up the urethral mucous membrane and then suture it to the skin."

Notwithstanding that this last paragraph destroys all claim of priority, which is after all but a small matter and one too much coveted, the writer feels constrained to bring this to the attention of the profession, believing that a service will be done thereby.

New Instrument.



A RUBBER-JAWED INSTRUMENT FOR ABDOMINAL SURGERY.

CHANNING W. BARRETT, M.D.

Professor of Gynecology, Chicago Clinical School; Adjunct Professor of Gynecology, College of Physicians and Surgeons (Medical Department, University of Illinois); Assistant Surgeon Marion Sims Hospital.

CHICAGO.

Surgeons feeling the need of an instrument that would handle without injury the delicate abdominal organs and hold them firmly yet gently, have made efforts to produce such an

A. The smaller forceps, two-thirds actual size. B. The jaw of the smaller forceps, actual size. C. The jaw of the larger forceps, actual size.

instrument temporarily by wrapping the jaws of the forceps with gauze. This is troublesome and bungling. Rubber sheaths have been prepared, but these fit the forceps loosely, do not sufficiently protect the tissues from the serrations on the jaws, are insecure in their hold, etc. Instruments with flat, smooth surfaced jaws have been made, but they crush tissue or take an insecure hold.

The accompanying illustration shows a forceps devised by the writer and used with great satisfaction. The shanks are constructed to give the proper spring, allowing the sensitiveness of touch to be used to the fullest extent. Two sizes are being made, for lighter and heavier work. The jaw consists of three parts: 1. The steel cup at the distal end of the forceps, its concavity looking toward the opposite jaw. 2. A moderately firm rubber disk, cupped on the opposing surface. 3. A screw and nut which fastens the rubber disk to the jaw. The nut is tightened on the external surface of the jaw so that the screw head on the internal surface is imbedded in the rubber disk, leaving a circular ridge of rubber to meet a like circular ridge on the opposing jaw, each with a cupped center. The forceps are so constructed that with the first catch on the handles the jaws just fail of meeting each other, coming together with the second catch and compressing each other with the third.

This, then, with elastic rubber jaws and light steel shanks, makes a forceps with which the delicate organs may be securely picked up without injury to the peritoneum or deeper structure. The rubbers will stand a number of boilings and when past their usefulness may be easily removed and replaced by another set. The construction of the forceps is such that the rubbers can not come off at an inopportune moment. It is surprisingly tenacious in its hold, even with the lightest bite, on wet, slippery tissues.

By the aid of these forceps one is enabled to do much of the abdominal surgery through a smaller opening or through the same opening with greater ease. The appendix, tube, bowel or ovary may be grasped and brought to the opening, using one finger as a guide. Should one bring up the wrong organ or tissue the grasp has done no harm; it may be released and another trial made. It is an efficient aid in suprapubic, double inguinal or vaginal celiotomy. It makes a useful instrument for holding the tube or ovary for resection, or the uterus for removal of fibroid. It may be used for picking up an injured ureter or a surgical gall duct or gall bladder. In pus tube it may be set on the broad ligament, leaving the pus tube between its shanks. A bowel may be held in the same way, setting the forceps on its mesentery. It lessens the amount of intra-abdominal manipulations, the instrument being used when otherwise the hand would be. I recall vividly the characteristically emphatic remark of the late Dr. Fenger to his assistant: "Don't I tell you a thousand times never to use your fingers when an instrument can be used?" This instrument does away with some of the necessity for rubber gloves and makes manipulation easier, providing they are worn.

It suggests itself as being useful for surgery in many other regions, if made in proper sizes and special shapes.

100 State Street.

The Contract Doctor.—The editorial in THE JOURNAL of the American Medical Association for April 11, 1903, entitled "The Battle of Clubs," should be read before every medical society throughout America, and serve as a clarion note of warning to the profession in this country, against the insidious but sure approach of an evil which, unless stopped, will sap the life blood of the profession, as it has done and is doing in Europe, where physicians are reduced to the degradation of making visits to well-to-do members of clubs for the beggarly fee of "8, 6, or even 4 pfennig" per visit. These clubs are organized with "the obvious object of reducing physicians' fees to the poor. Instead of being the recourse of the really poor, to whom a reduction of medical fees would be really justifiable, these societies are utilized by the well-to-do, thus defrauding the profession of its legitimate earnings." Now, in this country, as far as it has gone, it is even worse. Scores of societies, lodges and so-called protective and benefit associations have been and are being organized, not among the poor, but among well-to-do laboring classes and even including in their organization a class of more than well-to-do merchants and office employes. The principal aim of all these organizations is cheap medical service, with some benefits of secondary importance, while in many of them the object, pure and simple, is cheap medical service. In no other profession would such a condition of affairs be possible, and the cry of "commercialism" will not much longer be sufficient to quiet the protests that will come before our various societies, against the growth of this shameless, open underbidding of one alleged reputable physician against another, for the privilege of serving well-to-do people for a pittance. We, as a profession, all stand ready and willing to aid the suffering poor, and will always do more true charitable work than any other profession in the world, but charity does not demand that we make professional visits to people who are earning from forty to two hundred dollars a month for fifteen or even less than fifteen cents a visit and perform serious surgical operations for the same price.—*Northwest Medicine.*

THE ROLE OF SODIUM CHLORID IN THE PRODUCTION AND TREATMENT OF EDEMA.

Always a puzzling problem to pathologists, the processes involved in the production of edema seem to have been in part clarified by progress in the application of physical chemistry both to theory and practice, and the results have been made to yield much of practical value in the hands of French and Italian clinicians. Several years ago Loeb urged the importance of osmotic disturbances in accounting for edema, as of more significance than the merely mechanical factors of increased vascular pressure. According to him, the chemical changes occurring in tissues with oxygen supply decreased through venous stagnation, accounted for far more of the extravasation of fluid into the tissues than did the increased filtration that might result from the heightened vascular pressure present in the capillaries in any passive congestion, no matter how severe. Under conditions of decreased oxidation the normal steps of metabolism are so interfered with that there results an accumulation of soluble substances. On account of their concentration in the fluids of the cells and the tissue spaces there develops a rise in osmotic pressure in the tissues which leads to diffusion of fluids from the vessels to bring the osmotic pressure of the tissues into correspondence with that within the vessels, and a condition of edema is produced. The importance of this osmotic pressure was shown strikingly by Loeb in the observation that osmotic changes could readily be brought about in the muscles, causing a pressure more than 200 times as great as the maximum rise in pressure that can be produced in the pulmonic circulation by completely occluding the aorta. Such a comparison serves well to give the person unacquainted with the enormous forces of osmosis an inkling as to their great power.

Edema of nephritis has been perhaps most commonly ascribed to an inability of the kidneys to eliminate fluids, which, retained in the body, waterlog it into a condition of edema. The high blood pressure of the renal disease might also have been considered as leading to increased filtration into the tissues, as is supposed to be the case in obstructive edemas, were it not that interstitial nephritis with its high blood pressure usually has less edema than the parenchymatous form with a lower pressure. Injury to capillary endothelium by retained toxic substances has been considered to cause abnormal permeability with accumulation of plasma in the tissues. But none of these explanations has been altogether satisfactory. Determination of the molecular concentration of the urine by means of ascertaining its freezing point or its electrical conductivity has added not a little to an understanding of osmotic conditions in various renal diseases and their importance. Rather unexpectedly, perhaps, it has been found that sodium chlorid excretion and retention has possibly more to do with the disturbances of osmotic pressure in the tissues than any other ingredient of the urine.

If sodium chlorid is administered by mouth to a healthy individual the elimination of the salt is found to correspond pretty closely to the ingestion. In nephritics, however, this is far from the case. With interstitial nephritis the reaction is quite variable—in some cases the elimination increases and in some it does not, just as we have interstitial nephritis with and without edema. In parenchymatous nephritis, however, in which the predominating changes are in the secreting cells, the sodium chlorid output, generally much below normal, is not increased nearly in proportion to the amount taken in, and often there is no response at all. That the edema of nephritis bears a direct relation to this sodium chlorid retention is shown by the effect of administration or withdrawal of the chlorid from the diet of patients with edema. Deprivation of salt nearly always leads to a marked decrease in the edema while administration of salt is as promptly followed by increase in the swelling. Widal experimented with one patient, and by dietetic measures alone was able to alternately increase and decrease the amount of edema no less than nine times in a period of 62 days.

From these observations it would seem that in parenchymatous or epithelial nephritis the cells are less than usually permeable to sodium chlorid, as well as to other substances to perhaps a different degree. The sodium chlorid, accumulating in the blood, prevents elimination of water which is retained to keep the molecular concentration as nearly normal as possible. In other words, the water is retained not so much because the kidneys are at all impermeable to it as because they are impermeable to the salt. And, conversely, it is incorrect to assume that in parenchymatous nephritis the small excretion of solids is due to an insufficient elimination of water to carry them out. As the edematous fluids of the tissues have been found to contain more chlorid than the blood serum, it may be that the tissues have a greater affinity for the salt than has the blood, and as it accumulates in the tissue the water will accumulate there likewise.

Application of these facts to the treatment of edema has been most profitable. A diet poor in salt has been found very effective in the treatment of the dropsy of parenchymatous nephritis, and perhaps the best of such diets is milk. The success attained by the empirical use of milk is thus found to be due principally to its low

content of salt. It is not a matter of quantity or quality of albumin in the diet, for a meat diet without salt will decrease edema as quickly as a milk diet, while the addition of salt to the milk will cause the edema to recur rapidly. The French physicians who have given this matter its most complete test advocate the selection of certain cows for the milk supply and depriving them of salt, although this is not by any means essential for good results. Since the salt and not the albumin is the important factor in the diet, it is possible by judicious choice and preparation to secure quite a wide range of diet for the nephritic. Nor is parenchymatous nephritis alone to be benefited in this way. In cardiac dropsy, which was formerly supposed to be entirely a matter of increased blood pressure effects, the elimination of sodium chlorid is greatly impaired, apparently because of alterations in the renal epithelium resulting from the vascular stasis. Interstitial nephritis accompanied by dropsy is, of course, also to be considered in the same category, and in both of these good results have been obtained by the process of "dechloridation." In typhoid, pneumonia, and some other febrile diseases, there is also a retention of chlorids, whether from renal alterations or some other cause is not known. On this account it occurred to Chantemesse that the phlegmasia alba dolens of typhoid might be to a large extent the result of this hypochloruria, and he treated several patients on this basis with excellent results. The thrombosis itself, which he considers as rather a predisposing than an actual cause of the edema, seemed to disappear with great rapidity under this treatment. Again, the determination of the power to eliminate sodium chlorid, particularly the reaction of the elimination to changes of diet, is of much prognostic value. Courmont considers it of more value than the methylene blue test as an indicator of renal condition. Although so far this method of treatment has been chiefly utilized by the French and Italians, it promises so much relief, and is so entirely in accord with the facts already obtained both empirically and experimentally, that we may hope for more extensive application and reports as to its limitations.[1]

THE ANTITUBERCULOSIS CRUSADE.

The first lecture under the auspices of the Phipps Institute, Philadelphia, was delivered by Dr. E. L. Trudeau of the Adirondack Sanatorium. It was a happy idea to open the public campaign against tuberculosis with such an utterance[2] by a man to whom we owe more than to any one else—we think we can safely say—the movement for the sanatorium treatment of consumption in this country. Within only a few years have most of the institutions of this sort come into view, but the Adirondack Sanatorium under Dr Trudeau began as early as thirty years ago, when he, himself a seeker for health, sought the salutary climate of the Adirondack wilderness. The history of his efforts and the building up of the institution over which he now presides from its small beginning to its present development and international reputation is intensely interesting. It is a record of persistent effort and we may say of heroic philanthropy. The amount of self-sacrifice involved can be conceived best when we understand that the support of the institution from the beginning has depended on Dr. Trudeau's efforts, aided, as he says, by the able and often disinterested and self-sacrificing friends and assistants that from time to time he has had to call to his aid as the institution enlarged. He has kept the expenses to the patient within the limits of moderation notwithstanding the cost, and an annual yearly deficit has been made up to him by subscriptions from grateful ex-patients and whole-souled wellwishers of their race in the eastern cities. The therapeutic success of the institution has far outweighed its financial success. He shows that at least one-third of his patients have practically recovered and still a larger proportion have had their disease arrested or been materially improved. It is only a few years since the popular and even the medical idea of tuberculosis was that recovery from the disease was at best a happy accident and that therapeutic means, aside from certain climatic influences, were practically unavailing. If any one has helped to show the falsity of this idea in this country it is Dr. Trudeau.

Not the least interesting part of his lecture is the history he gives of his scientific work in the study of tuberculosis, in which he was practically a pioneer in this country as well as in the sanatorium treatment of the disorder. It is unnecessary to say that his work has been fruitful and that he anticipated in many respects the later work for which so much credit is now being given to Behring. That this work was done with the small facilities at his command is another instance of the often-demonstrated fact that the born investigator is to a certain extent independent of the highly-organized and elaborate facilities which modern research now seems to demand. Now, however, that Dr. Trudeau and his assistants have a well-appointed laboratory, we shall look for still better and more complete work in the future. Not the least important feature of the sanatorium work for which the Adirondack institution is largely responsible is the education of the public that it affords. It has been a sanitary missionary agency of the very highest rank and the lessons it has taught have not been confined to its immediate neighborhood or to this country alone, for wherever the treatment of tuberculosis is discussed the Adirondack Sanatorium results are quoted.

Whether or not we agree with some sanguine workers that our efforts are toward the complete eradication of tuberculosis as a scourge of humanity, there is no ques-

1. Original papers, several of which have already been abstracted in THE JOURNAL, can be found in the Bull. Soc. Méd. des Hôp. de Paris, June 12 to 26; the Lyon Médical, July 12 and 19; Semaine Médicale, June 24 and July 29, and others later, all of this year.

2. Medical News, October 24.

tion that the intelligent efforts now being made have already robbed this disease of many of its terrors and promise to still more reduce its mortality and render it, possibly in the not too distant future, a comparatively negligible factor in the death rate in civilized communities. Dr. Trudeau's lecture stands, therefore, as a sort of landmark showing what has been done and giving promise of what is yet to be done. A series of lectures of which it is the opening one will be continued, we understand, monthly, by such men as Drs. Osler and Gibbs of this country, and Pannwitz and Maragliano from abroad, with possibly Drs. Calmette of Lille, or Dr. William H. Welch, in addition.

It is not simply the outdoor life at the sanatorium, as Dr. Trudeau has in his practice and teaching all along pointed out, but also the close medical care and supervision, guided by thoroughly scientific study of the disease, that is required to rescue the victims of consumption and make the disorder itself less harmful. The publication of these lectures will go far, we think, to instill correct ideas in regard to the disease; there is need of this, for even in the profession itself there are many exaggerated and irrational notions extant in regard to its dangers and its avoidance. A crusade against tuberculosis, to be effective, must be thoroughly rational and must not be vitiated in any degree by the exaggerated and panicky fears that are encouraged by some of the writers on the subject. Dr. Trudeau has long pointed out by his Saranac experience that the dangers of communication of tuberculosis are easily avoidable, and he has also demonstrated that the established disorder itself is to a large extent amenable to therapeutic means at our command.

MEDICAL ASPECTS OF THE CHILD LABOR QUESTION.

At the recent annual meeting of the National Conference of Charities, Mr. Frederick L. Hoffman made some statements which are of interest to physicians. Mr. Hoffman is the statistician of a well-known life insurance company which makes a specialty of what is called industrial business, i. e., insuring working people and children for small amounts. His paper was entitled, "Medical and Social Aspects of the Child Labor Question." His first point is the lack of definite, trustworthy statistical evidence as to the effect of early labor on the physical and mental development of children, yet, as he reminds us, it is entirely practicable to obtain such evidence, and he urges that the whole matter be made the subject of a governmental inquiry. He says:

> The available statistical evidence, while not as complete as would be desirable, seems to prove conclusively that occupations with a trade life commencing very early, such as the textile industries, potteries, etc., experience an excessive death-rate at ages 15 to 24, and in many instances throughout life. . . . The laws of growth and the relation of health to growth are now so well understood that it would not be at all difficult to ascertain whether children employed at different trades are really physically injured, or stunted in their growth, or hindered in their development, physically as well as mentally, by such employment. It certainly would appear to me a paramount duty not to legislate along radical lines unless the basis of such legislation is all-convincing and established beyond the question of a possible doubt.

He also points out the fact that certain injuries and defects at least accompany the early school attendance of children, and in this connection he quotes Dr. Johnston of Washington, D. C., who believes that school instruction is commenced at too early an age, and who sums up the evidence thus far gathered as to the effect of school life in causing eye troubles, headache, sleeplessness and minor nervous disorders, and suggests that the beginning of formal school instruction should be at the age of 8 years, with the hope of avoiding overstrain of immature organisms.

On this subject, as well as on the subject of early child labor, there is much popular discussion of a very earnest sort which, however, entirely lacks a basis of carefully ascertained and analyzed facts. Mr. Hoffman is certainly right when he says that we need a body of reliable statistical evidence as to the effect of mental and physical labor of various kinds on the development of children. It is understood that a request for the appointment of a commission to obtain such evidence has been submitted to President Roosevelt. It is comparatively easy to secure the appointment of a federal commission, but not so easy, as experience has shown, to obtain from it the results its promoters desired. In this case if a commission were secured it would be especially the duty of the medical profession to urge the necessity for employing in such work the best scientific methods. A well-selected commission with adequate powers could certainly make a valuable contribution on which for a long time to come all efforts for reform in the legal protection of children should be based.

EUTHANASIA.

Every little while some misguided philanthropist comes out with a proposition to shorten the period of suffering of hopeless invalids, by gently putting them out of the way. The latest is from a New York clergyman in an address before a medical body. It is said that about one-third of the audience applauded him, but the applause, we take it, was not shown for this particular sentiment, but for the orator or the oratory. There is only one point of view the medical man can take on this subject, viz., that he has no right to trifle with a human life or shorten it by a second. Surely no thinking person can take any other stand. If it should be considered right to assist people out of the world on the pretense of saving them from suffering, the possibilities of using this plea by unscrupulous persons would become appalling. There are enough ways to relieve suffering without compromising life, and only such are legitimate. It is true that some people seem to live too long and that, on a purely utilitarian basis, old people past their productive period could be easily disposed of, but this is not the tendency of modern civilization. Any civilization that adopted such a course would be taking a long step backward toward savagery.

BRITISH AND AMERICAN ENGLISH.

There is a certain formula in use by the British reviewer of American books that reads something like this: "The English reader will, of course, be offended by the eccentricities of spelling affected by our transatlantic confrères," or something to that effect. It is interesting, therefore, in this connection to note a comment by the editor of one of our British contemporaries[1] which in a way criticises the spirit of conservatism in regard to all suggestions toward a simplification of the orthography of the language. It has its little fling, saying that "our American cousins, having no history and possessing no proprietary right to the language, being, in fact, only lodgers, so to speak, display no sort of reluctance to tamper with the ridiculous redundancies which our forefathers have bequeathed to us, and which our schoolmasters persist in maintaining to the discomfiture of the scholars and the curtailment of more useful studies." Aside from the little inaccuracies as to our proprietorship in the language, etc., the sentiment of the above quotation is good and "ridiculous redundancies" especially so. English as it is written in England, as well as "English as she is spoke" in that island, has its defects, and in neither case is it always and in all respects the best type of the common language of the Anglo-Saxon race. The British editor suggests that whether his countrymen like it or not, they will ultimately have to adopt the abbreviated transatlantic orthography. We hope that the change will be an earlier one than he seems to anticipate. It will not require any serious alteration of the mother tongue to make it a little less cumbrous in its spelling than is the prevalent insular British practice.

PLAGUE TREATMENT BY CARBOLIC ACID.

The ordinary dose of carbolic acid is usually given as from 1 to 3 drops, and 6 or 7 drops have been reported as producing very unfortunate symptoms, while half a dram is said to be almost inevitably fatal unless met by immediate adequate treatment. Nevertheless, we occasionally hear of what seems to be excessive dosage of this powerful agent. The Baccelli treatment of tetanus is an instance of rather heroic dosing, but the most remarkable usage of the remedy is reported from China in the treatment of plague. In a communication which is editorially noticed in the *Journal of Tropical Medicine,* October 1, Dr. J. C. Thompson reports treating cases of plague in Hong Kong with carbolic acid and in quantities of 144 gr. daily, divided into bi-hourly doses of 12 grains each. With these enormous doses he said he expected to see evidences of carbolic acid poisoning frequently appear, but it was practically unknown in his cases. In a few cases carboluria appeared, but the remission of one or two doses caused the symptoms to cease. Given well diluted, dyspeptic symptoms did not appear. As the result of his observations in 143 cases he believes this is the most hopeful method of treating plague thus far tried in Hong Kong and that carbolic acid is of undoubted value when given in doses sufficient to allow its concentration in the blood to exert its antiseptic action on the bacilli. It is not considered by him, however, as a specific remedy, but as an important aid in the treatment of this so generally fatal disorder. It is a matter worthy of investigation to determine, as the editor of the *Journal of Tropical Medicine* says, whether the toleration of these heroic doses by plague patients is a peculiarity of the disease or whether we must revise our ideas of the toxic character of the drug. We know that in many conditions a remarkable tolerance to certain agents is obtained and there is probably no reason for us to alter our ideas as to the dangers of carbolic acid under ordinary circumstances. If, however, the drug proves to be of as great value as these experiences indicate, the discovery is an important one.

1. Med. News and Circular, October 7.

Medical News.

ALABAMA.

Did Not Report Smallpox.—A negro employe of the Mobile postoffice was fined $10 for failing to report to the board of health the presence of smallpox in his family.

College Loses Appropriation.—The governor failed to sign the bill appropriating $20,000 to aid Mobile Medical College. He declared that he did not believe the bill received the constitutional majority, and that, further, he did not see that the source of the money had been provided.

Quarantine Ends November 1.—At a meeting of the Quarantine Board of Mobile Bay, the action of the Louisiana Quarantine Board was agreed to, which lessens, after October 15, quarantine regulations applying to Central American ports, and practically abolishes quarantine after November 1.

Personal.—Dr. Frank A. Lupton, Birmingham, has been elected a member of the board of censors of the Jefferson County Medical Society, vice Dr. Edward P. Riggs, resigned. ——Drs. Emmet K. Moon, Anniston, has been appointed county physician and Dr. William B. Arbery, Jacksonville, has been made physician to the county poor house of Calhoun County.

Colleges Open.—The Medical College of Alabama, Mobile, opened for its thirty-eighth annual session, October 8. Dr. George A. Ketchum, dean, delivered the address.——Birmingham Medical College opened for its tenth annual session, October 1. Dr. Benjamin L. Wyman, dean, Dr. Russell McW. Cunningham, lieutenant governor of the state, and Dr. John C. Le Grande, were among the speakers.

CALIFORNIA.

Anti-Expectoration Ordinances.—Ordinances prohibiting expectoration on sidewalks in San Rafael, under penalty of $25 fine, and on public conveyances in Sacramento under penalty of $50 fine, have been introduced.

Physician Exonerated.—Dr. R. E. Freeman, San Jose, against whom a complaint for performing a criminal operation had been made, has been discharged from custody, the preliminary examination having failed to sustain the charge.

Hospital on Wheels.—The San Pedro, Los Angeles and Salt Lake Railroad has added a hospital car to its equipment, fully equipped with medical and surgical supplies, and provided with an operating room, dispensary, private rooms and a ward.

Damage Suit Collapses.—In the suit brought by Martin Lathrop against Dr. Samuel J. Hunkin, San Francisco, in which the plaintiff claimed $50,000 damages for alleged malpractice, the plaintiff failed to appear, and the judge ordered a verdict for costs for the defendant.

Santa Ana Hospital Association.—At the annual meeting held October 9, the board of managers was re-elected, and Dr. John L. Dyer was elected president; Dr. Howard S. Gordon, vice-president; Dr. James P. Boyd, treasurer, and Dr. Charles D. Ball, secretary. The capital stock of the association was increased from $10,000 to $25,000.

San Joaquin Valley Medical Society Meets.—At the sixteenth semi-annual meeting held in Fresno October 13, the following officers were elected: President, Dr. James A. Moore, Hanford; vice-presidents, Drs. Robert E. Bering, Tulare, Harry W. Taggart, Stockton, and R. O. P. Phillips, Kingsburg, and treasurer, Dr. Thomas M. Hayden, Fresno. The secretary and assistant

secretary held over. After the meeting the society was banqueted by the Fresno Medical Society.

College Year Begins.—The College of Medicine of the University of Southern California, Los Angeles, opened for the fall term, October 8. The following changes in the faculty are announced: Dr. Walter Lindley, professor emeritus of gynecology; Dr. Carl Kurtz, professor of, and Dr. Wesley W. Beckett assistant in gynecology: Drs. David C. Barber, George L. Cole and W. Jarvis Barlow, professors of clinical medicine; Dr. Joseph Kurtz, professor of therapeutics; Dr. Randall Hutchinson, assistant professor of physical diagnosis; Dr. Stanley P. Black, professor of histology and pathology, and Miss E. L. Leonard, lecturer on histology and pathology.

Personal.—Dr. John R. Haynes, Los Angeles, has returned from England.——Dr. Andrew W. Hoisholt of the state hospital staff, Stockton, has returned from Germany.——Dr. Titian J. Coffey, Los Angeles, has returned after six months in the east.——Dr. Oscar W. Steinwand has been appointed city health officer of Selma.——Dr. and Mrs. Peter Jauss, Los Angeles, have returned from a six months' tour of northern Europe.——Dr. William J. Young, Stockton, has returned from Germany.——Dr. Joseph W. Jauch has returned after a four months' sojourn abroad.——Dr. and Mrs. F. R. Orella, San Francisco, have returned from Europe.——Dr. Albert S. J. Smith, San Jose, has gone to Europe to study for a year.

CONNECTICUT.

Personal.—Dr. Charles S. Stern, Hartford, chief medical inspector of the board of health, has resigned, and will go to Europe.

Forfeits Bail.—Dr. Edmund I. Thomson, New Haven, charged with performing a criminal operation, was not present when his case was called, and his bond of $1,500 was declared forfeited.

Connecticut Members of the Association.—At the second annual meeting of Connecticut members of the American Medical Association held at Savin Rock, October 13, Dr. Charles J. Fox, Willimantic, was elected president; Dr. Gustavus Eliot, New Haven, vice-president, and Dr. James M. Keniston, Middletown, secretary.

Gives Hospital to Greenwich.—Robert E. Bruce and his sister Sarah E. Bruce of Greenwich, have given a plot of land for a contagious disease and emergency hospital to the town. On the land are four buildings, one for smallpox, two for other contagious diseases and one to be used as an emergency hospital. The property is valued at $75,000.

DISTRICT OF COLUMBIA.

Barnes Hospital Addition.—An addition to Barnes Hospital at the United States Soldiers' Home has been contracted for at a price of $190,131.

Army War College Building Recommended.—The Secretary of War will recommend to congress an appropriation of $300,000 for the erection at Washington of a general military hospital and a similar amount for the Army War College.

Medical Supervisors Want Pay.—The board of medical supervisors and the various medical examining boards do not wish to serve longer without pay and they have asked for an appropriation of $2,500 from congress in order that the supervisors and examiners may each be paid at the rate of $10 for every meeting attended.

Health of District.—The report of the health officer for the past week shows the total number of deaths to have been 102, of which 65 were white and 27 were colored. There were 68 deaths, of which 38 were white and 30 were colored. There were 16 cases of diphtheria, 19 of scarlet fever and 210 of typhoid fever under treatment at the close of the week.

GEORGIA.

Offers to Take Father's Place.—Dr. Walter P. Rushin, Albany, has written the governor offering to serve out the life sentence for murder for which his father is now imprisoned in the state penitentiary.

College Opens.—Georgia Medical College, Augusta, opened for its seventy-second annual session, October 1. Dr. James B. Morgan delivered the address on "Higher Medical Education and the Prevention of Disease."

Smallpox in Middle Georgia.—Dr. H. F. Harris, secretary of the State Board of Health, reports that he found smallpox in every town he visited during a two weeks' tour of southern middle Georgia. He urges compulsory vaccination.

Fatal Hospital Fire.—A fire in the Grady Hospital, Atlanta, destroyed the male and female wards for colored people early on the morning of October 17, and only prompt and heroic action on the part of the hospital staff and employes, firemen, police and citizens prevented great loss of life. One negro woman, who was very sick, died after her removal from the hospital.

ILLINOIS.

Wabash Hospital Open.—The Wabash Middle Division Hospital, Decatur, was opened to receive patients October 5.

Hospital Dedicated.—The new addition to St. Elizabeth's Hospital, Danville, was dedicated, October 13, with appropriate ceremonies, following which a banquet was served to the staff and the visiting clergy by the Sisters of St. Francis.

Personal.—Drs. Henry W. Kendall, Quincy, and Albert G. Pickett, Chicago, were elected medical advisers of the Fiftieth Illinois Infantry, at its recent reunion.——Dr. Walter J. Brown, Danville, has been commissioned first lieutenant and assistant surgeon in the Illinois National Guard, and assigned to the artillery battalion.——Dr. Thomas N. Miller, Rockford, fell from a tree, October 8, and injured his spine.

Smallpox Thriving.—Dr. Joseph E. Kunkler, Bloomington, reports 23 cases in two public schools, the schools were ordered closed and an ordinance providing for compulsory vaccination was introduced in the city council, October 23.——Westfield has 17 cases in the isolation hospital, and a number quarantined at home. Public meetings have been prohibited and the public schools closed.——Dr. Heman Spalding of the Chicago Department of Health, after inspection of the situation at Lemont, reports that there are at least 25 cases there. Schools are closed and public meetings forbidden.——Belleville is reported as having 25 cases, with 4 deaths, and Freeburg, 3 or 4 cases.

Chicago.

An Award of Twenty Per Cent.—In a suit for $5,000 brought by Dr. Alexander Hugh Ferguson against Frank L. Loring and wife, for services rendered, the jury awarded the plaintiff $1,000.

Increase in Diphtheria.—Diphtheria continues to increase—106 cases being reported, as against 89 during the previous week. Reports come from all parts of the city, but the northwest section is most affected. Measles, scarlet fever and whooping cough are at a minimum.

The Week's Mortality.—For the week ended October 24, 442 deaths were reported, an annual mortality rate of 12.21 per 1,000, which compares favorably with 12.68, the rate of the previous week and 13.83, the rate for the corresponding week of 1902. Consumption, as usual, leads with 52 deaths; pneumonia follows with 49. Other principal causes were violence, 40; Bright's disease, 38, and heart disease, 32.

"Murderous Pneumonia."—In the current issue of the bulletin of the Chicago Department of Health is the following:

> The community is again facing the beginning of the murderous pneumonia season. Between the last of this month and the close of next May upward of 2,100 persons will die of pneumonia in Chicago, while from consumption—the "great white plague," which is practically monopolizing the attention and the efforts of the laborers in the field of preventive medicine—there will hardly be more than 1,300 deaths during the same period.
>
> Since the beginning of the last great pandemic of influenza, in 1889, there have been 33,861 deaths from pneumonia in this city and 29,980 from consumption—an excess of 11.4 per cent. of pneumonia mortality. During this period, that is, the last thirteen years, 1890-1902, the deaths from pneumonia have increased from an average of 117 in the 100,000 of population during the previous thirteen years, 1877-1889, to 179—an increase of nearly 53 per cent. Corresponding figures for consumption are 171 per 100,000 in the first period and 160 in the second—a decrease of a little more than 6 per cent.

MARYLAND.

Personal.—Dr. William L. Lewis, Kensington, has been appointed health officer for Montgomery County and secretary of the board of health in place of the late Dr. E. E. Stonestreet.

Baltimore.

Historical Club Election.—At the Johns Hopkins Hospital Historical Club Dr. Eugene F. Cordell was elected president and Dr. Thomas B. Futcher, secretary.

Deaths for the Week.—There were 171 deaths last week in the city, an annual rate of 16 per 1,000. There were 4 deaths from typhoid fever, and 9 from diphtheria.

Physician Wins Suit.—A suit against Dr. Edward J. Bernstein for $10,000 damages, for the alleged loss of the life of a child from meningitis following the enucleation of an eyeball, has been decided in favor of the defendant.

Personal.—Dr. Charles E. Simon has returned from Nova Scotia.——Dr. Charles W. McElfresh has been elected associate professor of clinical medicine in the University of Maryland, vice Dr. Morris C. Robins, resigned.——Among the visitors to Baltimore last week were the members of the Moseley Commission (referred to in these columns last week), sent from England to study American universities.

MASSACHUSETTS.

Milk for Sick Babies.—A total of $4,530 was contributed in Boston this summer for the fund which supplies modified milk to the sick babies of the poor.

Hospital for Melrose.—A new private hospital in which any physician may care for his patients, is to be established in Melrose by two graduate nurses of the Melrose Hospital Training School.

Personal.—Dr. Walter S. Carr, who for 19 years has practiced in North Adams, has gone to Colorado on account of ill health. ——Dr. Arthur K. Drake, assistant superintendent of the state Hospital, Tewkesbury, has been elected superintendent of the Lowell General Hospital.

Registration at Harvard Medical.—The registration of Harvard Medical School shows a total of 374 students, a decrease, accounted for by the graduation of a class admitted under the low standard. Harvard now requires an A.B., or its equivalent, for admission to the medical school.

Ether Anniversary.—The fifty-seventh anniversary of the first administration of ether for a serious surgical operation was celebrated by the trustees of the Massachusetts General Hospital by an open-air lunch and an inspection of the new out-patient department. Several thousand people were present.

Limit Authority of Staff.—The managing board of Milford Hospital has notified each member of the staff officially that "no operation of a dangerous character shall be performed without the consent of at least two members of the staff other than those on duty at the time of the performance of such operation."

No Diphtheria Epidemic.—There has been considerable newspaper excitement in Boston over the supposed existence of an epidemic of diphtheria among the school children. The City Board of Health has had cultures made by school inspectors in the districts mentioned and finds remarkable freedom from the presence of the germs in healthy throats. Several towns in the state, however, not far from Boston, are having many cases of diphtheria.

Bequests.—Dickenson Hospital, Northampton, received $1,000 by the will of Elizabeth D. Clapp of that city.——By the will of Dr. George Haven, Boston, Harvard Medical School receives $25,000, and a share in the residue, and the Boston Lying-in Hospital, with which Dr. Haven was long connected, receives $20,000, and an equal share in the residue.——In the will of Miss Mary P. Ropes of Salem, filed for probate, October 23, Salem Public Hospital is given $2,500.

MISSOURI.

Personal.—Dr. John G. Parrish, Sr., is critically ill at his home in St. Louis. Dr. Theodore Ilg, St. Louis, fainted in the street, October 12, and fractured his skull.

Charged with Illegal Practice.—J. A. Parker, J. C. Hoyt and F. A. Starback, Kansas City, were arrested October 12 on complaint made by the State Board of Health, charging them with practicing medicine without license. They gave bonds of $500 each, and trial is set for November 27.

New Surgical Society.—On September 21 the St. Joseph Surgical Society was formed with the following officers: Dr. Jacob Geiger, president; Dr. O. Beverly Campbell, vice-president; Dr. L. A. Todd, secretary; Dr. Thompson E. Potter, treasurer, and Drs. Charles H. Wallace and James W. Heddens, censors.

PENNSYLVANIA.

Quarantine of Allegheny Threatened.—The State Board of Health has notified the authorities of Allegheny that, unless they at once take active measures to stamp out smallpox, the board will probably quarantine that city.

Smallpox and Typhoid.—For the week ended October 24, 9 new cases of smallpox were reported in contrast to 54 for the previous week. Of typhoid fever 80 new cases occurred as compared with 103 for the previous week.

Work for the Insane.—The inmates of the insane department of the Philadelphia Hospital have little to occupy their time, except to help care for their apartments and to prepare and serve their food, so that they spend much of their time in idleness. Director Martin proposes to introduce horticulture, and to that end asks for the contribution of plants.

Experimental Inspection of Schools.—The committee on hygiene of the board of education has authorized the director of the department of health to assign a medical inspector to one of the public schools who shall inspect the pupils daily. This is to serve as an experiment as to the value of such work, and will go far in determining whether a system of inspection for all the schools will later be inaugurated.

Prosecutions for Adulterations.—Dairy and Food Commissioner Warren has ordered prosecutions against 365 liquor dealers in the state for adulteration. Of samples taken 85 per cent. are said to have contained salicylic acid. He has also ordered ten prosecutions in Philadelphia against violators of the lard and oleomargarin laws. Several manufacturers of compound lard have subscribed a large amount to defend the packers and dealers.

New Hospital for Consumptives.—The board of trustees of the Rush Hospital for the Treatment of Consumptives has approved plans for a new hospital building as an annex to the present hospital. The new building will accommodate 40 patients, doubling the capacity of the institution. One-fourth of the amount necessary for the addition, $20,000, has been appropriated by the state, and it is necessary for the friends of the institution to raise the balance.

WISCONSIN.

The New Year.—Milwaukee Medical College opened October 1 with a lecture by Dr. William J. Cronyn on "Medical Jurisprudence."

Superior's Deaths for the Year.—The report of the secretary of the local board of health for the year ended October 1 shows that 46 deaths were due to pneumonia, 40 to scarlet fever, and 30 to consumption during the year. The total of deaths for the year was 453.

Smallpox Closes School.—The German school at Weyauwega has been closed because of smallpox among the pupils. As no physician has been employed, it spread considerably before it came to the attention of the local authorities. A strict quarantine has been instituted and no further spread of the disease is anticipated.

Personal.—Dr. William C. Bennett, for seven years registrar of vital statistics of Milwaukee, has resigned, and Dr. F. E. Darling has been chosen to succeed him.——Dr. Albert F. Heising, Menominie, has returned from Europe.——Dr. F. C. Kovats, senior interne at the Emergency Hospital, Milwaukee, has resigned, and Dr. George K. Koeppel has been promoted.

GENERAL.

Assistant Surgeons U. S. Navy Appointed.—Five new assistant surgeons have been appointed in the Navy. There are still eleven vacancies in the medical corps.

Personal.—Dr. T. Storie Dixson, a member of the medical board of New South Wales, Australia, was in Chicago last week, and will visit Europe before his return to Sydney.

Assistant Surgeons U. S. Army Appointed.—At the recent examination of candidates for commissions as assistant surgeons in the Army, held in Washington, D. C., only 5 out of over 20 candidates who reported for the examination qualified. There are now eighteen vacancies remaining in the medical department of the Army. Another examination will be held in Washington next May.

Yellow Fever Refugees.—An interesting feature of the yellow fever outbreak in Monterey, Mexico, is the migration of a hundred or more people to groves near that city, where they live in tents. They thus are away from the crowded centers of infection. They prefer not to go further because of business or family ties. Many others have gone to adjoining towns. Only a few cases of yellow fever have occurred. There are other diseases reported there, including malaria, which have been confused with yellow fever.

The Enno Sander Prize.—All persons eligible to active or associate membership in the Association of Military Surgeons of the United States may compete for the prizes (first prize, a gold medal, value $100; second prize, a life membership in the association, value $50) offered by that association for the best essays on "The Relation of the Medical Department to the Health of Armies." In fixing the precedence of the essays submitted, the board will take into consideration—primarily—

originality, comprehensiveness and the practicability and utility of the opinions advanced, and—secondarily—literary character. Essays will consist of not less than ten thousand, nor more than twelve thousand words, exclusive of tables. Three typewritten copies of the essay must be sent marked with a nom de plume, and with the author's name in a separate envelope, as is usual in prize competitions. All essays must be received by Sept. 10, 1904, by Secretary James Evelyn Pilcher, Carlisle, Pa.

FOREIGN.

For spitting in a street car a man in London was fined $30. This is said to be the first prosecution there. The offense was accompanied with the use of foul language.

Sentence for Fatal Quack Practices.—The German charlatan, Runge, has been condemned to three months' imprisonment at Lauenburg on account of the death of a young woman whom he treated by extensive venesection and application of 22 leeches. She had a gastric ulcer and succumbed within a few days to debility from the loss of so much blood. Another charlatan, Scheibler, has been fined $75 at Berlin for fraudulent practices and the use of the title, professor.

Compulsory Accident Insurance of German Students.—The German universities are introducing the plan of compelling the medical students to insure themselves against accidents. At Greifswald it is obligatory for all the students in the departments of medicine and physics, but at Heidelberg it is obligatory only for those in the institutes of anatomy, pathology, hygiene, etc., in which there is possible danger of accidents, and also for the students working on the cadaver. The students must bear the expense of the insurance themselves, without aid from the university or state.

Fined for Insulting the Medical Profession.—A teacher and a capitalist of Elberfeld, Germany, have been fined $18 each for "insulting the medical profession." The first mentioned is president of the local association of "nature healers," and with the coöperation of the other advertised in the local papers a free course of lectures for the benefit of physicians on the diagnosis of eye affections. The physicians of the place regarded the advertisement as a deliberate insult and sued for damages. The court took the same view and fined the defendants as stated.

The Psychologic Aspect of the Humbert Frauds.—Dr. Fay comments in the *France Médicale* on the Humbert case as an example of what is possible to depravity plus hysteria. He says that as an illiterate country girl, Thérèse Humbert invented stories of concealed treasures while still a child, and as a young woman, a pronounced hysteric, she became convinced of the truth of what she was continually asserting in regard to the imaginary Crawford millions. This obsession persisted to the end, and still in prison where she is serving a five-year sentence. He adds: "Hysteria produces its saints and its sinners. Psychologists have always been interested in the record of the holy nun known as Sainte Thérèse who was affected with the gravest organic form of hysteria, hysteric paralysis with contractions. History now gives us in the life of the Humbert woman an amazing example of criminal human nature complicated by hysteria."

The Nuremberg Historical Medical Museum.—The last number of the *Deutsche Med. Wochenschrift* brings the report of the progress realized in this new institution which aims to preserve everything relating to the history of medicine in Germany. The report is from the hand of Dr. R. Landau, whose untimely death we recently chronicled. He describes with enthusiasm the many donations received during the year since its inception, and points out the great value to such a museum of original prescriptions from the hands of the dead masters, and urges their collection, also diplomas and other documents. One of the gems of the museum is a diploma given to an obstetrician in 1731, which is ornamented with designs introducing the surgical instruments used at that date. Another interesting historical feature is a collection of the first local pamphlets from the watering places. The success of this historical museum is now assured, if only as a memorial to Landau.

European Decorations for the Profession.—Two Spanish physicians were decorated by the King of Spain on the occasion of the International Medical Congress at Madrid. The order of the Cross of Alphonso XII was conferred on Dr. Larra y Cerezo and the Grand Cross on Dr. Cortezo, who is co-editor of the *Siglo Medico* and president of the International Medical Press Association. The *Siglo Medico* at once opened a subscription list to raise funds to present the insignia of the orders to the recipients, and now announces that sufficient contributions have been received for the purpose—about $170 and $213. These decorations are not always accompanied by the gift of the insignia, and in certain orders when they are presented it is with the understanding that they are to be returned to the sovereign presenting them on the death of the one thus honored. The Order of the Golden Fleece is one of this thrifty kind, and the badge thus acquires great historical value as it is passed from one holder to another. The Standard dictionary contains cuts of the most noted insignia, and our readers will remember that the order of the Dannebrog, founded in 1219, was conferred by the King of Denmark on Dr. Christian Fenger of Chicago, not long before his death. Several other members of the American Medical Association have also been thus distinguished by foreign potentates.

International Sanitary Conference.—Twenty-five powers are represented at this conference now in session at Paris. There are 69 delegates, 39 of whom are members of the medical profession. The invitation to the conference was issued by Italy, and the French ambassador to Italy, Mr. Barrère, presides over the meetings. France is represented besides by Brouardel, Proust, general inspector of the sanitary service in France, Roux of the Pasteur Institute, Calmette of Lille and three other physicians from the French colonies in Africa, with G. Louis, director of consulates. Great Britain is represented by de Bunsen of the British embassy, and two physicians, T. Thomson and F. G. Clemow, with Colonel Richardson of the Indian Medical Service and Mr. Alban. There are 4 official delegates from Germany, including Gaffky of Giessen and Nocht of Hamburg. The delegates from the United States include Surgeon Anderson, medical inspector of the European station, and Col. Gorgas, assistant surgeon-general, U. S. A., late of Havana, both members of the American Medical Association, with Dr. Giddings. The part played by the rats in the dissemination of the plague has been brought to light since the last international conference of the kind, and uniform measures to prevent infection from this source are under discussion. Another theme is the quarantine for the ships passing through the Suez canal. The wishes of Great Britain conflict with those of the other powers on this point.

A Warning to Wealthy Parents.—A very important lesson is drawn by the *Deutsche Med. Wochenschrift* from a recent sensational affair in Germany, urging the necessity for medical oversight of the children of wealthy parents. The two sons of a prominent Berlin banker were entrusted to a private tutor, who lived on a country estate or in the little town of Bayreuth with them while the parents were traveling or at home in Berlin. No one except the tutor was responsible for the lads, and their mental training seemed to be the only care of the parents. The tutor proved to be a typical case of extreme sadism, and during the months that the boys were under his charge maltreated them to such an extent that one has since died. If some local physician in the country town had been written to and requested to look after the children at brief intervals this terrible catastrophe might have been averted. Our exchange adds a warning to all parents, and especially to those of the upper ten thousand, to regard the health of their children as their most precious treasure, and not to leave the care for their physical welfare entirely in the hands of outside persons—no matter how "ideally" they may seem fitted for the task. In the case mentioned a number of extraordinary circumstances combined to keep the boys in their slavery and prevent its reaching the ears of the parents, who apparently regarded the boys' health and happiness as "neglectable quantities." The tutor has been sent to the penitentiary for eight years.

Decisions of the Prussian Medical Court of Honor.—In a recent decision the court stated that misdemeanors, etc., on the part of physicians, outside of their professional work, come within the jurisdiction of the court of honor, as such proceedings conflict with the honor of the profession. In another case a local court of honor had fined a physician for selling his practice to his successor. Appealing to the central court of honor the physician showed that the price received, $750, was in payment for the vehicles, etc., valued at $800, and that the practice had not been included in the bargain, and the sentence of the lower court was reversed. In another case a physician was fined for associating himself in business with a charlatan. He offered testimony to prove that the charlatan had contracted with him to refrain altogether from any connection with medical affairs, and, hence, he considered that the man had ceased to be a charlatan. The decision of the court was to the effect that any business association with a charlatan is *per se* an offense against professional ethics, but as the physician had severed at once his connection with the charlatan as

soon as he learned of the disapproval of the court, this was accepted as a mitigating circumstance and the lightest penalty imposed. Another physician had examined a deaf and dumb workingman, but in making out the certificate later did not think of this defect and testified that he was sound. The local court of honor censured the physician but did not fine him, stating that a single act of negligence is not sufficient to justify the assumption that a physician is habitually negligent. The higher court of honor took up the case and proclaimed that neglect of proper carefulness, even in a single instance, is sufficient to show that the physician does not exercise his profession in a conscientious manner. The failure to specify the deafmutism of the subject when taking the notes for an official certificate, is sufficient grounds for the assumption of negligence, and a penalty was therefore imposed.

PARIS LETTER.

Radical Treatment of Eclampsia.

Dr. Maury, former interne of the Paris hospitals, has written a thesis recently on the treatment of eclampsia, in which he strongly advocates Bounaire's treatment, consisting in removing the child as soon as possible. If labor comes on during eclampsia, it should be hastened, whatever may be the date of the pregnancy. When such is not the case, it should still be carried out when the attack of eclampsia is severe. In some cases the condition of the mother is such that the only means of saving the child is to perform the "accouchement forcé." After the beginning of the eighth month it is well to do this if eclampsia does not respond quickly to the treatment.

Microbes Necessary to Nutrition.

A German physician, Schottelius, has been carrying out some experiments on some chickens which are highly interesting as tending to show that some bacteria are necessary to life. Five new-born chickens were given sterilized food, and though they ate much more than other chickens, none was able to live more than eleven to twenty-nine days. The digestion seemed to take place normally, but there was no increase in size. Schottelius made another experiment, which consisted in giving some of these chickens a culture of *Bacillus coli gallinarum*. The chickens began to grow larger immediately and no anomaly was noticed.

Destruction of Rats by Carbonic Acid.

In the French Review of Hygiene a method of destroying rats on board ship has been recently described by Dr. Jacques of Marseilles. Carbonic acid was used, and for a space of 120 cubic meters 40 cubic meters were employed. The carbonic acid was brought to the hold of the vessel by means of a long pipe, which divided off into four smaller pipes passing into the merchandise. The hold was kept closed three hours, and then thoroughly ventilated by means of the same apparatus. Fifty-two rats which had been placed in the hold were found dead. One advantage of this operation is its absence of odor, and the fact that it can hurt no merchandise.

Radiography of Gallstones.

At a meeting of the Academy of Sciences held last month Drs. Mauclaire and Infroit described how they had obtained a radiograph of gallstones. This is, it seems, the first time that such a result has been obtained. A small tube, which was "osmo regulateur," and charged by a static machine with eight places, was placed at 75 centimeters from the radioplate, on which the patient was placed directly. A bandage of linen, 30 centimeters large, served to compress the abdomen. The tube was but slightly penetrating and the pose only lasted 10 minutes.

Novel Treatment of Gastro-enteritis.

At a meeting held by the Academy of Medicine October 13, Dr. H. de Rothschild, one of the members of the well-known family of that name, described the results of his treatment of infantile gastro-enteritis. It seems that six thousand infants under a year of age die on an average every year in Paris from this disease. Dr. de Rothschild has milk centrifuged so as to remove the butter, then acidified by using pure cultures of lactic acid; 30 to 60 cubic centimeters are then given to a child. After this treatment the temperature dropped in a short space of time, and the condition of the patients improved, the most noticeable fact being that they increased in weight. Out of 14 cases treated in this manner, a complete cure was obtained in 13 cases, and in one case only was there a relapse, which ultimately was followed by a cure.

The Relations of Cancer and Ulceration of the Stomach.

Duplant of Lyons, a pupil of Professor Tripier of Lyons, published in 1898 a work in which he declared that it was not proven that cancer ever succeeded ulcer of the stomach, and went so far as to say that such an event never took place. Dr. Andistere has just published a thesis in which he proves that such a transformation may take place, and is not rare. This is most frequently seen in ulcers situated in the prepyloric region and begins by the borders of the ulcer. A diagnosis can be made out by the persistence of the morbid symptoms after prolonged treatment, especially the pain. The prognosis is much more grave than that of ordinary cancer, as complications of both diseases may supervene.

Marriages.

John D. Cantwell, M.D., Davenport, Iowa, at Ackley, Iowa, October 8.

Edwin W. Poinier, M.D., to Miss Lela M. Peet, both of Chicago, October 27.

Lewellys F. Barker, M.D., Chicago, to Miss Lilian Halsey, at Baltimore, October 29.

Frederick H. Baetjer, M.D., to Miss Mary Y. Carey, both of Baltimore, October 14.

Richard C. Norris, M.D., Philadelphia, to Miss Grace Thompson-Vogt, October 14.

W. W. Coleman, M.D., Lawndale, Ill., to Miss Bida Dunham, near Lincoln, Ill., October 14.

Harry G. Watson, M.D., to Miss Adelaide Marie Erichs, both of New York City, October 14.

Joseph Marshall Flint, M.D., to Miss Anne Apperson, at Pleasanton, Cal., in September.

Edward Homer Gee, M.D., to Miss Lavinia Logan Gant, both of Zanesville, Ohio, October 14.

Louis H. Cisler, M.D., Marietta, Ohio, to Miss Carol S. Nye, at Brookline, Mass., October 12.

Wallace W. Robinson, M.D, Portland, Me., to Miss Addie E. Bowden of Chicago, October 28.

Glasgow Armstrong, M.D., to Miss Jessie May Bowling, both of Staunton, Va., October 14.

Julian F. Chisholm, M.D., Savannah, Ga., to Miss Nannie E. Levering, at Baltimore, October 15.

J. A. Johnson, M.D., Bottineau, N. Dak., to Miss Emma Babler of Humboid, Wis., October 7.

Homer Samuel Warren, M.D., to Miss Charlotte A. Van Housen, both of Chicago, October 15.

Herman Carl Merker, M.D., Chicago, to Miss Nina A. Williams of Rochester, N. Y., October 14.

Edward Sanborn Smith, M.D., Macon, Mo., to Miss Emily Frey, at Washington, D. C., October 14.

Victor L. Zimmerman, M.D., Brooklyn, N. Y., to Miss Margaret King of New York City, October 14.

Charles P. Aling, M.D., Marine Mills, Minn., to Miss Genevieve McCool, at Hillsboro, Ill., October 23.

Harry Clemm Hyde, M.D., Baltimore, to Miss Mary Catherine Duncan, at Norfolk, Va., October 14.

Travis Scott, M.D., Pleasant Plains, Ill., to Miss Witty, at her home near Newmanville, Ill., October 14.

Leonidas A. Koontz, M.D., to Miss Rachel J. Corley, both of Sutton, W. Va., at Baltimore, October 11.

Charles H. Spencer Williamson, M.D., to Mrs. Josephine Gillette Stillwell, both of Chicago, October 15.

Joseph Francis Ward, M.D., Brooklyn, N. Y., to Miss Elizabeth R. Hawkins, at Baltimore, October 15.

Deaths.

Jean Fresne Chauveau, M.D. Geneva (N. Y.) Medical College, 1853, a member of the American Medical Association, New York State Medical Association, New York Academy of Medicin, New York County Medical Society, and New York Neurological Society, attending physician at the French Hospital for twenty years, and for fifty years a practitioner of New York City, died at his home, October 17, aged 72.

Maurice Fieschor Pilgrim, M.D. Howard University, Washington, D. C., 1884, once vice-president, and at the time of his death chairman of the executive council of the American

Electro-Therapeutic Association, died at his home in New York City, October 18, from pneumonia, after a brief illness, aged 45.

Sidney S. Willis, M.D. College of Physicians and Surgeons, New York, 1890, a member of the American Medical Association, and one of the staff of St. Elizabeth's Hospital, Appleton, Wis., died at that institution, October 14, from typhoid fever, after an illness of ten days, aged 35.

John L. Waldie, M.D. Long Island College Hospital, Brooklyn, N. Y., 1896, died at his home in Brooklyn, N. Y., October 18, from kidney disease, after an illness of two weeks, aged 31. He was a member of the staff of St. Mary's Hospital and of the Kings County Medical Society.

Albert Nott, M.D. University of Vermont, Burlington, 1869, some-time dean of the Boston College of Physicians and Surgeons, and of the Tufts College Medical School, died suddenly at his home in West Newton, Mass., October 10, from rheumatism of the heart, aged 53.

J. W. Carleton, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1869, of Sisseton, S. Dak., a member of the American Medical Association, was found dead in Dry Wood Lake, October 14. He is supposed to have died from heart disease.

Robert Aberdein, M.D. Bellevue Hospital Medical College, New York City, 1867, of Syracuse, N. Y., who had retired from practice three years ago on account of ill health, died at the Hospital of the Good Shepherd, Syracuse, October 18, aged 57.

W. D. Hoyt, M.D. Jefferson Medical College, Philadelphia, 1854, a member of the American Medical Association, and one of the oldest practitioners of Rome, Ga., died at his country home near Farrill, Ala., October 16, from septicemia, aged 75.

James I. McConnell, M.D. Atlanta (Ga.) Medical College, 1884, a member of the International Association of Railway Surgeons, died at his home in Napoleonville, La., October 7, after an illness of one month.

John George Neal, M.D. Kentucky School of Medicine, Louisville, 1890, died in Santa Rosa, Cal., from septicemia, October 11, three days after an operation for abscess in the hip-joint, aged 38.

Hamill M. Alexander, M.D. University of Pennsylvania, Philadelphia, 1876, a member of the American Medical Association, died at his country home at Conewago, Pa., October 13, aged 52.

Albert F. Sawyer, M.D. Harvard University Medical School, Boston, 1852, one of the physicians in attendance on President Garfield, died at his home in San Diego, Cal., September 29, aged 84.

DeWitt Clinton Clark, M.D. New York University, 1878, was stricken with paralysis, September 24, near Orting, Wash., and died at the home of his daughter in Puyallup, September 30, aged 68.

David A. T. Bjorkman, M.D. College of Physicians and Surgeons, Chicago, 1898, of Evanston, Ill., died from tuberculosis at the Glockner Sanitarium, Colorado Springs, Colo., October 14.

Marsh H. Smith, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1875, of Manchester, Ill., died suddenly from heart disease while on a train at Dwight, Ill., October 16.

George C. Baker, M.D. University of Tennessee, Nashville, 1894, of Greenville, Ill., died suddenly from apoplexy, October 9, while making a professional call at Woburn, Ill., aged 42.

Ludwig S. Filbert, M.D. Pennsylvania Medical College, Philadelphia, 1847, died at his home in Philadelphia, October 19, from acute gastritis, after an illness of twelve days, aged 78.

John Ellis Wright, M.D. Marion-Sims College of Medicine, St. Louis, 1899, of Oak Grove, Ark., died from consumption, October 12, at the home of his father in Grandview, Ark.

Hugh P. Smith, M.D. Memphis (Tenn.) Medical College, 1858, died at his home in Goldthwaite, Texas, October 7, aged 73. He became blind and retired from practice in 1900.

Ossian W. Goss, M.D. Harvard University Medical School, Boston, 1882, a member of the American Medical Association, died at his home in Lakeport, N. H., October 8, aged 47.

George P. Kaemmerling, M.D. College of Physicians and Surgeons, Chicago, 1902, was found dead in bed in his office in Port Washington, Wis., from heart disease, October 3.

Richard Carnegie, M.D. Trinity College, Dublin, for ten years medical officer of an Allan liner, died recently in his berth on board the *Bavarian*, at the port of Montreal, aged 38.

Mark J. Morton, M.D. University of Tennessee, Nashville, 1885, died at his home in Fallcreek, Tenn., October 13, aged 40.

Daniel M. Pratt, M.D. Castleton (Vt.) Medical College, 1851, died at his home in Washington, D. C., October 12, from paralysis, after an illness of two weeks, aged 74.

Willam H. Graves, M.D. Southern Medical College, Atlanta, Ga., 1898, died at his home in Webster, Fla., October 2, from typhoid fever, after an illness of two weeks.

Frank C. Le Blond, M.D. Medical College of Ohio, Cincinnati, 1874, was found dead in his office at Celina, Ohio, from neuralgia of the heart, October 7, aged 53.

James Y. Bradfield, M.D. Medical College of Georgia, Augusta, 1858, of Daingerfield, Texas, died at Sulphur Springs, Texas, October 6, suddenly, from heart disease.

A. C. Bourbeau, M.D. Laval University, Quebec, 1902, honor man of his class, died at his home in Ste Agathe, Que., September 30, from typhoid fever, aged 25.

John Dudley Keegan, M.D. Cleveland Medical College, 1869, died at his home in Columbus, Ohio, October 9, from throat disease, after a short illness. aged 78.

William L. Wright, M.D. Memphis (Tenn.) Hospital Medical College, 1894, died at his home in Powder Springs, Ga., from an overdose of morphin, October 14.

Joseph N. McCrary, M.D. Louisville Medical College, 1893, of Whitesburg, Ky., died, October 16, from consumption, after a lingering illness, aged 33.

Jesse C. Rowley, M.D. Rush Medical College, Chicago, 1891, died suddenly from heart disease at his home in Prairie du Chien, Wis., October 21.

B. C. Seaton, M.D. Jefferson Medical College, Philadelphia, 1873, died at his home in Bolivar, Pa., October 9, from paralysis, aged 55.

William Willigman, M.D., of Mineral City, Ohio, died at his home, October 10, after a short illness, aged 58.

Deaths Abroad.

A. Fochier, M.D., professor of obstetrics and an eminent surgeon of Lyons, France, died in October, aged 66, succumbing in the halls of the university to a fulminating attack of angina pectoris. He was president of the local surgical society and had long been a member of the city council. Of all his numerous contributions to science the best known, perhaps, is his method of inducing aseptic abscesses with turpentine as a revulsive measure, the so-called "fixation abscesses."

Sophie Frances Hickman, M.D., a member of the staff of the Royal Free Hospital, Gray's Inn Road, London, disappeared August 15, and, despite all efforts, no trace of her was found until October 18, when a headless body, identified as hers by trinkets, was found in a wood at Richmond. She was about 30 years of age.

Miscellany.

Success of Sodium Bicarbonate for Dressing Wounds.—Levassort applies the bicarbonate directly to the wound, sifting it freely over and packing the cavity with asceptic gauze, sometimes mixing it with the gauze. He leaves this dressing for fifteen to twenty days, merely drawing up a small piece of the gauze and cutting it off every two or three days. When the last of the gauze is removed the depths of the wound are found filled with red, almost erectile, granulations, and healing is soon complete. He does not drain except in abdominal surgery. The bicarbonate does not injure the tissues, but aids in osmosis and stimulates and provides a nourishing fluid for the young cells that develop. Their proliferation is so intense that they crowd out all microbian elements and grow into and transform fibrous cicatricial or degenerated tissues, so that it is not necessary to remove the latter to the extent generally believed. In his communication to the *Jour. de Méd de Paris* he illustrates a typical case out of his five years' experience with this method, and describes a number of others.

A Profession, Not a Trade.—The professional man, like others, must live, and must earn a wage. But he has only one quality of service to sell—his best. No matter whether there be any return for that service or not, the service is his best. The true ideal of a profession is that want will be accepted rather than a fee for the performance of some act that is dishonorable, or *unprofcssional*. The army takes high place in the list

of professions. Ruskin, the great sage, reaches the true reason when he says of the soldier: "He holds his life at the service of the state. Our estimate of him is on this ultimate fact—of which we are well assured—that, put him in a fortress breach, with all the pleasure of the world behind him, and only death and his duty in front of him, he will keep his face to the front." Here, then, we have the real essence that must ever distinguish the professions from the trades—service first, wage second.—*Canada Lancet.*

Hot Saline Solution in Treatment of Scrofulous Glands.—Unterberger has adopted the *douche filiforme salée* of the Biarritz physicians in his treatment of scrofulous glands in the neck, and states that it accomplishes surprisingly favorable results. He applies a stream of a concentrated saline solution, as hot as can be borne, to the gland for one to three minutes and follows this with hot compresses wet with saline solution, a tablespoonful of salt to a glass of water. At Biarritz the natural thermal saline waters are used at a temperature of 104 F. with a pressure representing 7 meters. Afterward the patient is given a warm saline bath and dried with hot towels, and is ordered to lie down for nearly an hour. The osmotic tension throughout the body is increased by the salt and the general metabolism accelerated, while the jet on the glands stimulates retrogressive metamorphosis. He states, in his communication to the *St. Petersb. Med. Woch.*, xxvii, 32, that his success with scrofulous glands has led him to try this method of treatment also for subcutaneous infiltrations and bone and joint affections. The results have been highly satisfactory.

Santonin in Tabes.—In 1901 Negro announced that in 8 out of 11 cases of tabes the fulminating pains were arrested by administration of santonin, while two others were much improved and only one proved refractory. Combemale reports in *Echo Méd.*, vi, 26, his experience with it in 16 cases of various nervous affections. In 7 cases not the slightest effect was appreciable, whether the patients took larger or smaller doses, in shorter or longer courses. These were all cases of neurasthenia or ordinary neuralgia. On the other hand, in the 9 cases of tabes the fulminating pains were unmistakably arrested in 5 by the medication. Negro's dose was 15 cg. of santonin in three doses of 5 cg. each at an hour's interval, given during the attack. Combemale gave smaller amounts, longer continued, but has become convinced that Negro's method is preferable. He found that gastric crises followed the subsidence of the fulminating pains in one case in which the santonin had been given continuously for a maximum period. He remarks that xanthopsia is the first sign of incipient intoxication and requires suspension of the drug, but at this early stage of intoxication there is no danger of serious consequences from it. He is inclined to try a preventive course of 15 cg. in future when fulminating pains are imminent.

After Reorganization, What?—If the reorganization of the medical profession gave no further results than increased harmony and unity in the general profession of medicine it would be well worth all it costs, but as a matter of fact this expected result is one of the very least of probable good benefits. One of the first things to be looked after by the officers, particularly the president and the secretary, of the various new county societies, is the preparation of interesting scientific programs. One of the greatest objects that the committee on reorganization had in mind was the promulgation of scientific spirit in the various county societies. It is expected that in the local society the very best work will be done. The younger men of the profession should do their full share of original research and in correctly recording their observations of cases. The older men in the profession are fitted to draw conclusions from these observations, together with their own from earlier years. The joint results from such work will accomplish a great deal in preventing much of the radicalism that now does our profession so much harm. The university extension system could be very easily applied to the work of a society. Men who are recognized leaders in their chosen fields would gladly give of their time to this work. Considerable time might well be spent on the subject, "Business Methods." Surely no profession needs to give greater consideration to this subject than does the medical profession.—*Iowa Medical Journal.*

The Non-Members of Medical Societies.—Why is it that a large majority of all practitioners are not members of a medical society? In part this is due to apathy of the officers and failure to present an attractive program, but more often the fault is in the men. Perhaps given over wholly to commercialism, a doctor feels it a waste of time to join a society, and so it is if he is in the profession only for the money he can get out of patients, without regard to the sacred obligation to put himself in the best possible position to do the best that is known for them. More frequently, I fear, the "dollar-doctor" is a regular frequenter of the society, knowing full well how suicidal in the long rung is isolation from the general body of the profession. The man who knows it all and gets nothing from the society reminds one of that little dried-up miniature of humanity, the prematurely senile infant, whose tabetic marasmus has added old age to infancy. Why should he go to the society to hear Dr. Jones on the gastric relations of neurasthenia when he can get it all so much better in the works of Einhorn and Ewald? He is weary of seeing appendices, and there are no new pelvic viscera for demonstration. It is a waste of time, he says, and he feels better at home, and perhaps that is the best place for a man who has reached this stage of intellectual stagnation.—*Dr. Osler before the New Haven Medical Association.*

Book Notices.

THE PRINCIPLES AND PRACTICE OF HYDROTHERAPY. A Guide to the Application of Water in Disease. For Students and Practitioners of Medicine. By Simon Baruch, M.D., Professor of Hydrotherapeutics in the New York Post-Graduate Medical School and Hospital. Second Edition, Revised and Enlarged. With Numerous Illustrations. Cloth. Pp. 496. Price, $4.00 net. New York: Wm. Wood & Co. 1903.

The appearance of this second edition so soon after the previous one indicates its usefulness and the timeliness of the work. It is the only satisfactory treatise on the subject in our language. The author has cut down the material which he deemed necessary in his first edition to support his beliefs in the general use of hydrotherapeutics and has added a chapter on insanity based on the recorded observations of practical alienists. We believe the present edition will be received with the same favor as was the first, and perhaps even with more, since the first volume has educated the medical public to some extent in the use of water. The book should be read by every general practitioner. While hydrotherapy is overdone in some respects, as in the Brand treatment of typhoid fever in some cases, there are many other ways—beside the full bath—in which the antithermic and tonic effects of water can be obtained; not a few valuable uses of water are too little used. This work of Dr. Baruch will continue to be the standard text-book on its subject in this country.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., Professor of Nervous and Mental Diseases and Head of Neurological Department, Northwestern University Medical School; and Frederick Peterson, M.D., President New York State Commission in Lunacy. Fourth Edition, Thoroughly Revised and Enlarged. With 338 Illustrations. Cloth. Pp. 922. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

This edition of this well-known work contains the later additions to our knowledge on the subject. Church has included in the text the data in regard to nerve degeneration furnished by Ballance and others, and has also included herpes zoster as a nervous disease. The subject of intermittent claudication is also considered as well as the myoclonic type of epilepsy and special attention is given to certain points in diagnosis, etc. The department of the book on insanity by Peterson has been enlarged by a review of the problems of psychiatry as shown in the recent work of German investigators; in other words, a review of the more recent work in this line by Ziehen, Wernicke, and Kraepelin, which has been contributed by Dr. Adolph Meyer, director of the New York Pathologic Institute. This forms a valuable addition independent of the rest of the psychiatric part of the book. New

cuts have been added to the work, and it will undoubtedly maintain its place as one of the leading, if not the leading, text-book on its subject in this country.

MODERN BULLET WOUNDS AND MODERN TREATMENT, with Special Regard to Long Bones and Joints, Field Appliances and First Aid. Part of the Alexander Essay for 1903. By Major F. Smith, D.S.O., Royal Army Medical Corps. Cloth. Pp. 99. Price, $1.20 net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

This is a part of the Alexander prize essay for 1903. It is but a small book, but will be of practical value to those who are interested in this branch of modern surgery.

SERUM THERAPY, BACTERIAL THERAPEUTICS AND VACCINES. By R. T. Hewlett, M.D., M.R.C.P., D.P.H. Lond., Professor of General Pathology and Bacteriology, King's College, London. Cloth. Pp. 262. Price, $1.75. Philadelphia: P. Blakiston's Son & Co. 1903.

The author has attempted to give a concise account of the preparation of antitoxins and the treatment of diseases therewith and antisera and various other substances, vaccines, etc., obtained from bacterial cultures and the like. With this he gives brief directions as to the making and testing of various preparations, though, as he says, the data are not complete, and only practical experience can make one thoroughly skillful and competent. He has briefly noticed other somewhat allied substances, such as typhoid extract of jez, cancroin, etc. The book will be a convenient one of reference to the physician who wishes to be posted on these substances.

DISEASES OF THE SKIN. An Outline of the Principles and Practice of Dermatology. By Malcolm Morris, Consulting Surgeon to the Skin Department, St. Mary's Hospital, London. With 2 Colored Plates and 58 Plain Figures. New Edition. Flexible Cloth. Pp. 642. Price, $2.50. Chicago: W. T. Keener & Co. 1903.

This third edition of Morris' handbook brought out for American readers is one of the more convenient as well as complete of the smaller handbooks on dermatology and deserves to be widely read. It is especially convenient in its compactness, and, while no work on this subject can be absolutely complete within its compass, it is as nearly so as can probably be demanded. Dr. Morris says that care has been taken not to alter the character of the volume in expanding it from an elementary manual to a treatise, and it will be all the more acceptable to many general practitioners for just this reason.

ANNUAL REPORTS OF THE SUPERVISING SURGEON-GENERAL OF THE MARINE-HOSPITAL SERVICE OF THE UNITED STATES. For the Years 1900 and 1901. Paper. Pp. 736 and 652 Respectively. Washington: Government Printing Office.

These are interesting documents. Beside the ordinary matter which such reports contain there are a number of instructive pathologic and clinical reports. A portion of real historical interest is the correspondence and history of the action in regard to bubonic plague at San Francisco in 1901, an instructive episode in public sanitation. It is to be hoped that no other sanitary officer will be subject to the persecution and abuse that Dr. Kinyoun received in San Francisco. Taken altogether the reports of these two years are valuable contributions to sanitary literature.

State Boards of Registration.

COMING EXAMINATIONS.

State Board of Examiners of Alabama, Montgomery, Nov. 1-10.

Oklahoma Medical Examining Board, Enid, Nov. 10.

Committee of the Connecticut Medical Society, City Hall, New Haven, Nov. 10.

Board of Registration in Medicine of Massachusetts, State House, Boston, Nov. 10-11.

State Board of Health of West Virginia, Point Pleasant, Nov. 10, 11, 12.

Nebraska State Board of Health, Lincoln, Nov. 11.

Board of Registration of Medicine of Maine, Augusta, Nov. 11.

Board of Medical Examiners of the State of California, City Hall, San Francisco, Dec. 1.

New Mexico Board of Health, Santa Fe, Dec. 7.

Examining Board of Medical Society of Delaware, Dover, Dec. 8.

Board of the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, Dec. 8.

Ohio State Board of Medical Registration and Examination, Columbus, Dec. 8, 9 and 10.

Illinois July Report.—Dr. J. A. Egan, secretary of the Illinois State Board of Health, reports the written examination at Chicago, July 22, at which, out of 153 applicants, 149 passed and 4 failed. We have prepared from this a summary by colleges, as follows:

COLLEGE.	No. Passed.	No. Failed.	Max. Grade.	Min. Grade.	Average of Those Who Passed.	Average of Those Who Failed.
Northwestern Univ., Chicago...	26	0	91	81	87.07	.....
Rush Medical College, Chicago..	50	0	93	79	86.68	.....
College of P. and Surgs, Chicago	7	0	91	76	84.42	.....
Harvey Medical College, Chicago	14	0	89	78	83.57	.....
Jenner Medical College, Chicago.	11	2	87	65	81.45	67
Illinois Medical College, Chicago	5	0	83	76	81.20	.....
Amer. Med. Miss. Coll., Chicago.	2	0	83	81	82.00	.....
Hahnemann Med. Coll., Chicago.	2	1	85	67	83.50	67
Chicago Homeo. Medical College.	2	0	87	76	81.50	.....
University of Michigan.....	3	0	90	86	87.66	.....
University of Iowa.....	3	0	85	81	83.66	.....
Eclectic Med. Inst., Cincinnati..	2	0	84	78	81.00	.....
Hosital Med. College, Louisville.	2	0	89	82	85.00	.....
Kentucky School of Medicine...	2	0	84	84	84.00	.....
Bennett Medical College, Chicago	1	1	80	72	76.00	.....
Amer. Coll. of M. and S., Chicago	1	0	75	75	75.00	.....
Coll. of Med. and Surg., Chicago	1	0	82	82	82.00	.....
Baltimore Medical College.....	1	0	87	87	87.00	.....
Woman's Med. College, Chicago.	1	0	76	76	76.00	.....
Milwaukee Medical College.....	1	0	82	82	82.00	.....
M. Sims-Beaumont Med. College.	1	0	87	87	87.00	.....
Jefferson Med. Coll., Philadelphia	1	0	84	84	84.00	.....
Kentucky University	1	0	76	76	76.00	.....
Amer. Medical College, St. Louis	1	0	83	83	83.00	.....
Johns Hopkins University.....	1	0	89	89	89.00	.....
Keokuk Medical College.....	1	0	80	80	80.00	.....
Cornell University	1	0	88	88	88.00	.....
Medical College of Ohio.....	1	0	81	81	81.00	.....
University of Palermo, Italy....	1	0	86	86	86.00	.....
University of Naples, Italy.....	1	0	84	84	84.00	.....
University of Genoa, Italy.....	1	0	84	84	84.00	.....
Cleveland Homeo. Med. College..	1	0	83	83	83.00	.....

The following are the grades in detail attained by the candidates of schools having 3 or more representatives:

Northwestern University: A grade of 91 was attained by 2; 90 by 6; 88 and 87 each by 3; 86 by 4; 85 and 84 each by 2; 89, 83, 82 and 81 each by 1.

Rush Medical College: 93 and 92 each by 1; 91 by 3; 90 and 89 each by 5; 88 by 4; 87 by 11; 86, 83 and 82 each by 3; 85 by 6; 84 and 81 each by 2; 79 by 1.

College of Physicians and Surgeons: 91, 90, 89, 87, 80, 78, 76 each by 1.

Harvey Medical College: 89, 88, 86, 85, 84 and 78 each by 1; 87, 83, 81 and 79 each by 2.

Jenner Medical College: 87, 84, 79, 78, 69 and 65 each by 1; 81 and 80 each by 2; 82 by 3.

Illinois Medical College: 83 by 3; 81 and 76 each by 1.

Hahnemann Medical College: 85, 82, 67.

University of Michigan: 90, 87, 86.

University of Iowa: 85, 85, 81.

Rhode Island Report.—Dr. G. T. Swarts, secretary of the Rhode Island State Board of Health, reports the examination held at Providence, R. I., Oct. 1 and 2, 1903, as follows: Number of subjects, 7; questions, 70; percentage required, 75; examined, 16; passed, 15; failed, 1. The examination was a written one.

FAILED.

244	R.	University of Naples.....	1899	73.9

* Special oral examination October 15.

The questions asked were as follows:

ANATOMY AND PHYSIOLOGY.

1. Give a brief description of the temporal bone, and state with what bones it articulates. 2. Describe the tarso-metatarsal articulations. 3. Describe the sacrum and give comparative osteology of same. 4. Describe the nerve mechanism of mastication. 5. Give the physical and chemical characters of protoplasm. 6. Describe the (*a*) fixed, and (*b*) ameboid cells of connective tissues. 7. Describe the mode of secretion and discharge of bile and give the average quantity daily secreted by man. 8. Give the chemical composition of human milk. 9. Give the quantity of water in 1000 parts of (*a*) blood, (*b*) gastric juice, (*c*) teeth, (*d*) milk. 10. Name the muscles of the internal femoral region.

CHEMISTRY AND MATERIA MEDICA.

1. What chemical may be used to neutralize the action of hydrochloric acid when taken as a poison? 2. What pathologic changes are found in connection with a highly alkaline urine? 3. Name some of the chemical changes which take place as the result of action of bacteria. 4. What gas is present in a case of death by suffocation? Give its formula and what chemical is its antidote. Give its symbol. 5. What effect does formaldehyd have on the usual action of dirty milk, and what on the human system, or should that chemical be used by the farmer? 6. In what way does aqua pura or oxygen serve as a therapeutic agent? 7. Give uses of calomel at the present day and mention two forms or combinations in which it is used. 8. Give the doses of two of the coal tar products used as a febricide and care to be used in their administration. 9. Give uses, doses and form in which quinin should be administered. 10. Describe the therapeutic value of alcohol in the human system.

PATHOLOGY.

1. Describe the details of incisions at autopsy for the purpose of removing and examining the kidneys. 2. Describe the appearance of the inner walls of the bladder in chronic cystitis. 3. What are the most common pathologic changes found in the aged? 4. What is the causative factor in septicemia following the penetration of a rusty nail in the foot? 5. Describe the appearance of a heart affected with fatty degeneration. 6. Describe the appearance of tuberculosis of the intestines. 7. What pathologic change is a cause of alopecia? 8. What are the pathologic and mechanical changes which produce spinal curvature? 9. What internal or external lesions may be found present as causative of a hemorrhage in the abdominal cavity? 10. In case of death from retention of a foreign body in the lungs what pathologic changes would be found?

SURGERY.

1. Name the several forms of stricture of the esophagus. Give treatment of cicatricial stricture. 2. Give symptoms, prognosis and treatment of acute lymphangitis. 3. Give varieties and complications of hare-lip. Describe Golding-Bird's operation for same. 4. Give diagnosis and treatment of basal fractures of the skull. 5. Give treatment of gunshot wounds of the face. 6. How would you make a diagnosis of paralysis of the muscles below the seat of a fracture? Give prognosis and treatment of same. 7. Give signs and symptoms of fracture of the femur, with treatment of same. 8. Describe operation for ligation of the posterior tibial artery in its middle third. 9. Give symptoms of moist gangrene. 10. How would you treat a case of dermatitis venenata?

THEORY AND PRACTICE.

1. Describe a case of acute laryngitis; cause; treatment. 2. Differential diagnosis between cerebral hemorrhage and embolism. 3. Describe a case of chronic interstitial nephritis. 4. Lobular pneumonia. 5. Delirium tremens; give treatment. 6. Scarlet fever; give treatment. 7. Diagnosis and treatment of endocarditis. 8. Of gastroduodenitis. 9. Of appendicitis. 10. Of hypertrophic cirrhosis of liver.

OBSTETRICS AND GYNECOLOGY.

1. Give period of a normal term of gestation and causes which may shorten that period. 2. Name three of the most common causes of premature birth. 3. What procedures should be employed to resuscitate an infant apparently dead? 4. How diagnose the presence of a ruptured uterus and what treatment is called for? 5. When may anesthetics be used to advantage during labor? 6. Diagnose a case of prolapsus uteri and give cause for and treatment of same. 7. Describe differential diagnosis between ovarian cyst and fibroid of uterus. Give causes for dysmenorrhea. 9. Give treatment for gonorrheal vaginitis. 10. What pathologic conditions may produce a cystitis?

HYGIENE AND MEDICAL JURISPRUDENCE.

1. What judgment should be used in the use of baths in health? 2. How may we prevent the spread of communicable diseases? 3. Suggest a desirable method of ventilating a school room. 4. By what means and through what channels is the plague disseminated? 5. Why does suburban residence and occupations produce longer life, and why is the mortality in typhoid fever greater in the country? 6. Name three of the most common forms of insanity. 7. How may we compare a partly damaged bullet found in the tissues with others found in a revolver? 8. A physician is on trial for the death of a friend. The evidence is only circumstantial, although motive is in evidence. What especial examinations should be made at autopsy of deceased? 9. What stains of the clothing may appear like blood stains, and how may they be distinguished? Give one example. 10. A man dies a short time after being struck on the head with a bottle. What evidence would you require to satisfy a jury that that blow was the cause of death?

Medical Organization.

California.

PASADENA MEDICAL SOCIETY.—The members of this society have decided to affiliate with the Los Angeles County Medical Society in conformity with the standard plan.

MENDOCINO COUNTY MEDICAL SOCIETY.—This society was organized at Ukiah, October 8, with a charter membership of 12. Drs. Curtis G. Kenyon, Andrew W. Morton, and Philip M. Jones, all of San Francisco, a committee from the trustees of the state medical society, were present and aided in the work of organization. Dr. Edward W. King, Ukiah, was elected president; Dr. William N. Moore, Ukiah, vice-president, and Dr. Charles A. Poage, Hopland, secretary-treasurer.

SHASTA COUNTY MEDICAL ASSOCIATION.—On October 11 this society perfected its organization on the standard plan and elected the following officers: Dr. Olin J. Lawry, Redding, president; Dr. John M. Read, Redding, vice-president; Dr. R. F. Wallace, Redding, secretary; Dr. C. W. Harper, Redding, treasurer, and Drs. Adelbert B. Gilliland, Cottonwood, C. W. Bryant, Redding, and John M. Read, Redding, trustees. The membership of the society will include physicians of Trinity County.

Indiana.

MORGAN COUNTY MEDICAL SOCIETY.—Councilor Dr. Myron A. Boor of the Fifth District organized a county branch of the state medical society, on the standard plan, at Martinsville, recently.

PUTNAM COUNTY MEDICAL SOCIETY.—The physicians of the county met at the office of Dr. Clinton T. Zaring, Greencastle, October 13, and with the aid of Dr. Myron A. Boor, Terre Haute, councilor for the Fifth District, reorganized the county society in conformity with the standard plan.

SHELBY COUNTY MEDICAL SOCIETY.—Physicians from various parts of the county met at Shelbyville, October 12, and reorganized the county society, adopting the standard constitution and by-laws, and electing the following officers: President, Dr. Charles C. Cook, Gwynneville; vice-president, Dr. Bayard G. Keeney, Shelbyville; secretary, Dr. Franklin E. Ray, Shelbyville; treasurer, Dr. Frank Campbell, Shelbyville, and censors, Drs. Henry M. Connelly, Flat Rock, Henry E. Phares, Shelbyville, and I. W. Inlow, Blue Ridge.

Iowa.

MAHASKA COUNTY MEDICAL SOCIETY.—At the regular meeting of the society at Oskaloosa, October 9, Dr. David C. Brockman, Ottumwa, councilor for the Sixth District, was present and aided in the reorganization on the standard plan. The following officers will hold over until the annual meeting in January next: Dr. Joseph T. Coveny, president; Dr. Joseph C. Barringer, vice-president; Dr. Herman C. Homer, secretary, and Dr. Samuel W. Clark, treasurer, all of Oskaloosa.

Louisiana.

OUACHITA PARISH MEDICAL SOCIETY.—With the aid of Dr. John M. Barrier, Delhi, president of the state society, the physicians of the county organized a society at Monroe, October 17, on the standard plan. Dr. W. B. Miller, Fouche, was elected president; Dr. W. E. Pugh, vice-president, and Dr. Robert W. O'Donnell, secretary and treasurer.

ASCENSION PARISH MEDICAL SOCIETY.—With the assistance of Dr. John M. Barrier, Delhi, this society was organized at Donaldsonville, October 8, and the standard constitution and by-laws adopted. Dr. William M. McGailliard was elected president; Dr. Tuite H. Hanson, vice-president, and Dr. Paul T. Thibodaux, secretary-treasurer, all of Donaldsonville.

TANGIPAHOA PARISH MEDICAL SOCIETY.—Dr. John M. Barrier, Delhi, president of the Louisiana State Medical Society, organized this society on the standard plan at Amite City, October 19, with an initial membership of 18. Dr. John H. Ellis, Kentwood, was elected president; Dr. Charles S. Stewart, Amite City, vice-president, and Dr. J. S. LeNoir, Amite City, secretary and treasurer.

North Carolina.

ROWAN COUNTY MEDICAL SOCIETY.—This society met at Salisbury, October 12. Dr. Thomas E. Anderson, Statesville, councilor for the Eighth District, was present and offered for consideration the standard constitution, which was adopted. Drs. J. M. Flippin, Henry T. Trantham and John Whitehead, all of Salisbury, were elected censors.

Oklahoma.

NORTH OKLAHOMA MEDICAL ASSOCIATION.—This association was organized at Blackwell, October 13. Dr. Mark M. Lively, Blackwell, was elected president; Dr. Edward Hooper, Braman, vice-president; Dr. Henry F. Alexander, Blackwell, secretary, and Dr. Allen Lowery, Blackwell, treasurer.

Philippine Islands.

PHILIPPINE ISLANDS MEDICAL ASSOCIATION.—In order to comply with the standard requirements, a number of physicians, both American and native, met at Manila, September 15, and organized this association, adopting the standard constitution and by-laws, and electing the following officers: Dr. John Donelon, president; Drs. Trinidad H. Pardo de Tavera and Jose Albert y Mayoralgo, vice-presidents; Dr. William E. Musgrave, secretary-treasurer, and Drs. P. C. Freer, John R. McDill, Richard P. Strong, John Mage and Herbert W. Yemans, all of Manila. At the meeting a charter was granted to the Manila Medical Society.

Wisconsin.

MARATHON COUNTY MEDICAL SOCIETY.—Physicians of Marathon County met at Wausau, October 10, and organized a county society on the standard plan.

LANGLADE COUNTY MEDICAL SOCIETY.—The physicians of Langlade County met at Antigo, October 9, and organized a county society, with the aid of Dr. John M. Dodd, Ashland, councilor for the Tenth District. The following officers were elected: President, Dr. Ignatius D. Steffen, Antigo; vice-president, Dr. Michael J. Donohue, Antigo; secretary and treasurer, Dr. Frank I. Drake, Antigo; censors, Drs. Michael J. Donohue, Antigo, Flatley, and Fred V. Watson, Antigo, and delegate to the state medical society, Dr. Ignatius D. Steffen, Antigo.

GREEN COUNTY MEDICAL SOCIETY.—Fourteen physicians of the county met at Monroe, October 16, and elected Dr. George W. Roberts, Albany, temporary chairman. After discussion of the plan of organization proposed by the national, and endorsed by the state association, the organization was perfected by the adoption of the standard constitution and by-laws, and the election of the following officers: Dr. Samuel Moyer, Monroe, president; Drs. Thomas W. Nuzum, Brodhead, and Henry B. Gifford, Juda, vice-presidents; Dr. William B. Monroe, Monroe, secretary; Dr. John G. Randall, Monroe, treasurer; Dr. Nathan A. Loofbourow, Monroe, delegate to the state society; Dr. Eli W. Fairman, alternate, and Drs. George W. Roberts, Albany, William B. Gnagi, Monroe, and Elias J. Helgesen, New Glarus, censors.

Society Proceedings.

COMING MEETINGS.

Hawaiian Territorial Medical Society, Honolulu, Nov. 7.
Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.
Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 15.
Western Surgical and Gynecological Association, Denver, Dec. 28-29.

PENNSYLVANIA STATE MEDICAL SOCIETY.

Fifty-third Annual Meeting, held at York, Sept. 22 to 24, 1903.

(*Concluded from page 1040.*)

Differential Diagnosis Between Friedreich's Disease and Insular Sclerosis.

DR. F. SAVARY PEARCE, Philadelphia, read a paper by this title. Insular sclerosis, as a rule, begins between the ages of 20 and 30. The gait may vary, being spastic, cerebellospastic or cerebellar. In the latter case would occur the confusion. The occurrence, however, of rigidity with nystagmus, staccato speech and intention tremor would aid in diagnosis. Apoplectic attacks, bulbar symptoms and the liability for the disease to completely recede, it is said, would all seem to make diagnosis clear in the majority of cases.

Inflammation of the Middle Ear in Diseases of Children.

DR. THEODORE J. ELTERICH, Allegheny, said that statistics regarding the occurrence of unrecognized middle ear inflammation are so startling that it becomes a duty to examine the ears of young babies suffering from diseases apparently trivial. Of 100 cases examined by Ponfick 35 per cent. of the cases of acute middle ear inflammation occurred in infants dying of acute gastro-enteritis. In all these cases there had been no pain or external ear symptoms. The diagnosis of middle ear inflammation in young infants the writer considers well-nigh impossible in some instances. As soon as aural complication is detected gentle inflation should be made by the Politzer bag. The application externally of dry heat and the instillation of atropin dissolved in glycerin and water are recommended; about 1 grain of atropin to 1 dram each of glycerin and water. In addition 1 or 2 grains of phenacetin or an opiate should be given if required. For the congestion of the tympanic membrane he recommends bromid of sodium in small and repeated doses. These measures failing, paracentesis with the knife under strict antiseptic precautions should be done.

The Result of One Year's Medical Treatment of Gastroptosis.

DRS. J. DUTTON STEELE and ALBERT P. FRANCINE, Philadelphia, described observations on 30 cases and concluded that: 1. In one-fifth of the cases the symptoms were due to downward displacement of the stomach. 2. Long continued mechanical support does not permanently restore the stomach to its normal position. 3. In cases in which the gastric symptoms are caused by uncomplicated downward displacement of the stomach the results of medical treatment have been very gratifying.

DISCUSSION.

DR. THEODORE DILLER, Pittsburg, had observed in two cases of neurasthenic women great benefit from the use of abdominal supports.

DR. R. H. GIBBONS believes that cases which have gone beyond a very slight dilatation should be treated surgically, preferably by Beyea's method, which he considers the best operation invented in modern times.

DR. S. SOLIS-COHEN took exception to the use of the term neurasthenia as a result of gastroptosis or displaced kidney. While there might be a collection of symptoms resembling in some degree neurasthenia, the condition was not neurasthenia, which was a distinct disease or nerve exhaustion.

DR. DILLER said that he regarded his two patients as having a vitality decidedly below par and that he considered the condition of the viscera dependent on the neurasthenia. Neurasthenia he considers a matter, not of the neurons alone, but of the whole organism. In agreement with this he had understood Dr. Steele to say that in four-fifths of the cases he regarded the falling of the viscera a symptom of neurasthenia.

DR. ERNEST LAPLACE agreed with Dr. Diller. Supportive treatment alone, he believes, will not put the patient into the condition in which he will absorb the proper nutrition for his tissues, and only the surgeon can remove the cause of depression. Afterward medical treatment can make them perfectly healthy.

DR. J. D. STEELE agreed with Dr. Diller's statement of the case, but he would consider gastroptosis a complication rather than a symptom in neurasthenia. It is considered that gastroptosis is probably a link in the vicious circle.

Decapsulation of the Kidney for Chronic Bright's Disease.

DR. JAMES TYSON gave a historical summary and reported a case in detail. He regards the operation as at least life prolonging, as curative in some and as applicable to cases other than those of nephritis in its various forms. Dr. Tyson assumes that the operation should not be done until medical measures have been thoroughly applied; yet it should not be deferred until the patient is moribund. He considers parenchymatous nephritis more favorable for operation than interstitial. Further application of the operation is suggested in cases of obstinate so-called idiopathic hematuria.

DISCUSSION.

DR. S. SOLIS-COHEN spoke of a case of hematuria in which there was floating kidney, much enlarged, accompanied with albuminuria, hyaline and granular casts, and which was operated on by Dr. J. Chalmers DaCosta. It being considered unwise to decapsulate the kidney, the capsule was incised in various directions. Improvement was immediately manifest and the woman has gained forty pounds in weight. There is still occasional hematuria, but stone has not been proven to be present.

DR. RICHARD HENRY GIBBONS does not feel that the benefits of the operation come from the relief of tension, for there is but little tension in nearly all cases. He referred to a case of hematuria in which the kidney was opened but no stone found, and which, nevertheless, recovered.

Modern Treatment of Fractures with Special Reference to the Lower End of the Humerus and the Bones of the Leg.

DR. HIRMA S. MCCONNELL, New Brighton, read this paper at the Wednesday afternoon session and suggested the advisability of more thorough instruction in medical schools, and gave in detail the technic to be pursued.

DR. EDWARD MARTIN, Philadelphia, read a paper on "Surgical Treatment of Recent Fracture of the Patella," in which he stated that all fractures of the patella, in which the fragments are separated more than half an inch, or which are

attended by marked immediate joint tension, should be treated by the open method.

Retrodisplacements of the Uterus.

Dr. J. M. Baldy, Philadelphia, in this paper expressed the belief that very few cases of this condition occur as a primary condition. He condemned the free use of pessaries and thought that the intra-abdominal was the preferable operation for shortening the round ligament.

DISCUSSION.

Dr. E. E. Montgomery, Philadelphia, felt that Alexander's operation should never be performed as a matter of choice, and that ventrofixation and ventrosuspension should only be performed when the patient is past the menopause. He believed the intra-abdominal operation devised by Ferguson to be the preferable one.

Dr. Richard H. Gibbons, Scranton, felt that either the operation devised by Webster of Chicago or Edebohls' modification of the Alexander operation were excellent procedures, but the latter was condemned by Dr. Baldy, in closing the discussion, on account of the danger of hernia.

Some Observations on the Pathology and Treatment of Empyema.

Dr. P. Y. Eisenberg, Norristown, advocated: 1. Free evacuation of the pus cavity. *a*. Aspiration. *b*. Free incision. *c*. Resection of a rib or ribs. 2. Irrigation of the pus cavity. 3. Drainage.

DISCUSSION.

Dr. W. W. Keen, Philadelphia, reported a case illustrating the necessity for adequate drainage and the removal of the enormously thickened serous membrane in the chronic cases.

Dr. Lowell M. Gates, Scranton, said that in most of the cases there should be resection of the ribs and drainage by means of drainage tubes.

Dr. Richard H. Gibbons, Scranton, recommended gauze drainage.

Dr. Ernest Laplace, Philadelphia, called attention to the possibility of multiple abscesses and the necessity for accurate diagnosis.

Dr. Herman B. Allyn referred to the difficulty of differentiating cases in which there was bronchial breathing from pneumonia.

Dr. John B. Roberts, Philadelphia, felt that resection of the ribs was in many cases unnecessary and should be determined by the study of the individual case.

Dr. G. Franklin Bell, Newberry, felt that the operation should depend on the bacterial element and the size of the abscess cavity.

Dr. George W. Guthrie, Wilkesbarre, felt that resection of the ribs was necessary in comparatively few cases, and recommended an incision in the most dependent portion of the pleura and the insertion of a double drainage tube.

The Treatment of Suppurating Ulcers of the Cornea.

This paper by Dr. Lewis H. Taylor, Wilkesbarre, was read by Dr. Ernest U. Buckman, Wilkesbarre, in which the author urged the importance of prompt attention to all wounds of the cornea and when they show a tendency to virulent suppuration the application of the galvanic cautery.

DISCUSSION.

Dr. B. Alexander Randall, Philadelphia, spoke with favor of the method employed by Lippincott of cauterizing the cornea with hot water, and preferred eserin to either cocain or atropin.

Dr. W. H. Dudley felt that the method of Lamb of New York of circumscribing the area of the ulcer and thus preventing its extension was more efficient than trying to destroy it.

Papers on Puerperal Sepsis and Appendicitis.

"The Treatment of Puerperal Sepsis" was read by Dr. E. E. Montgomery, Philadelphia, in which he emphasized the importance of differentiating between germicidal infection and the results of putrid intoxication, and outlined the course of treatment appropriate to each.

"Differences in the Management of Appendicitis and Salpingitis" was read by Dr. George E. Shoemaker, Philadelphia, in which he stated that in salpingitis conservation might be justifiable, while in appendicitis radical procedure was the only safeguard.

"One Year's Work in Appendicitis" was read by Dr. John B. Deaver, Philadelphia, in which he reported 566 cases operated on between Sept. 1, 1902, and Sept. 1, 1903, with a mortality of 5 per cent. He divided the cases into three classes: 1. Those suffering from diffuse peritonitis, in which 16 were operated on with five deaths, or 31 per cent. 2. Those in which there was a localized abscess, numbering 183 cases with 22 deaths, or 12 per cent. mortality. 3. Those in which the disease was confined to the appendix, numbering 367, with 3 deaths, or 0.8 per cent. mortality. In conclusion he urged the necessity for early operation.

Other Papers Read.

The following papers were also read:

"Gynecologic Therapy, a Plea for Operative Conservatism," by Dr. Charles F. Spangler, Kan. "Three Unusual Vesical Cases, with Operation," by Dr. Ella B. Everitt, Philadelphia. "The Obstetric Experience of a Country Physician," by Dr. H. C. McKinley, Myersdale. "The Management of the Pus Appendix," by Dr. G. W. Guthrie, Wilkesbarre. "The Value of the Differential and Absolute Leucocyte Count in Cases Simulating Appendicitis," by Dr. A. Snively, Waynesboro. "The Treatment of Suppurative Appendicitis," by Dr. Ernest Laplace, Philadelphia. "Perforated Gastric and Duodenal Ulcers, with Report of Three Cases Operated On," by Dr. John H. Gibbon, Philadelphia. "Extensive Decapsulation Combined with Fixation of Every Movable Kidney to Prevent Bright's Disease; Complete Decapsulation for the Cure of Bright's Disease and for the Relief and Prevention of Puerperal Convulsions," by Dr. R. H. Gibbons, Scranton. "Four Cases of Penetrating Wound of the Orbit," by Dr. A. R. Craig, Columbia. "A Sarcoma of the Maxillary Antrum and Orbit," by Dr. J. F. Klinedinst, York. "Statistics Relating to 1,135 Cases of Refraction Occurring in Private Practice," by Dr. M. V. Ball, Warren. "An Investigation of Certain of the Reflexes and Sensory Phenomena and the Condition of the Eye-grounds, Based on a Study of 103 Healthy Young Men," by Dr. Theodore Diller, Pittsburg. "The Upper Respiratory Tract," by Dr. J. C. McAllister, Ridgeway. "The Syphilitic Nose and Throat," by Dr. Charles P. Grayson, Philadelphia. "Some of the More Unusual Results of Movable Kidney," by Dr. Charles P. Noble, Philadelphia. "Surgical Treatment of Facial Palsy," by Dr. Charles H. Frazier, Philadelphia. "Drugs Useful in Cardiac Affections," by Dr. S. Solis-Cohen. "A Fatal Case of Chorea, Complicated by Endocarditis, Pericarditis and Nephritis," by Dr. Augustus A. Eshner. "Four Cases of Malignant Diseases of the Lungs," by Dr. J. C. Lange, Pittsburg. "Affections of the Eye Associated with Diseases of the Contiguous Sinuses," by Dr. S. D. Risley, Philadelphia. "The Operative Treatment of Strabismus," by Dr. Wendell Reber, Philadelphia. "The Differential Diagnosis of Exophthalmos," by Dr. Joseph E. Willets, Pittsburg. "Danger Signals of Intracranial Infection from the Pneumatic Cavities of the Ear and Nose," by Dr. B. Alex. Randall, Philadelphia. "The Use of Myelocene in Catarrhal Deafness," by Dr. Walter B. Weidler, Lancaster. "Some of the More Infrequent Causes of Obstruction of the Common Bile Duct," by Dr. Levi J. Hammond, Philadelphia. "The Results of the Surgical Treatment of Ascites Occurring in Cirrhosis of the Liver, with Report of a Case," by Dr. Herman B. Allyn, Philadelphia. "Abdominal and Pelvic Surgery without Ligatures; Electro-Thermic Hemostasis," by Dr. Andrew J. Downes, Philadelphia.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-ninth Annual Meeting, held at Memphis, Oct. 7 to 9, 1903.

(*Concluded from page 1042.*)

In the surgical section a paper on "Technic of Mirror Sight" was read by Dr. Allen De Vilbiss, Toledo, Ohio, who discussed why the general practitioner should understand the subject, and offered a few suggestions how to learn it.

Principles in the Treatment of Chronic Otitis Media Purulenta.

Dr. John F. Barnhill, Indianapolis, stated that all aural discharges, except those due to tubercle or cancer, are curable by the methods used for similar conditions in other parts of the body. Cure would be simple and easy were it not for the concealed and inaccessible situation of the disease. All treatment is likely to be unwisely directed until the cause is ascertained. If, after all parts have been thoroughly treated that are accessible to surgical and medical measures through the route of the external meatus, the disease continues, sound surgical principle dictates that the disease should be followed to its origin and thoroughly eradicated. This necessitates, in most instances, the radical mastoid operation. Wilde's incision or gimlet trephining of the mastoid is not based on sound surgical principles, and should be entirely abandoned.

DISCUSSION.

Dr. J. A. Stucky, Lexington, Ky., said that there are those who still believe in the use of laudanum and sweet oil, yet it

is well known that laudanum had no place as a local application in a chronically discharging ear. Furthermore, any oil except glycerin is positively contraindicated. He emphasized the importance of thoroughly cleansing the ear, saying that while this was apparently a simple procedure, nine times out of ten it was not half done.

Nasopharyngeal Adenoids.

DR. J. A. STUCKY, Lexington, Ky., presented the following deductions: The obstructive and non-obstructive adenoid tissue, when diseased, is a menace to health, hearing, mental and physical development, and should be radically dealt with, as it is far more serious in its effects than disease and enlargement of the faucial tonsils. Frequently, when the pharyngeal tonsil is thoroughly removed, the enlarged faucial tonsils rapidly assume normal size and function.

DISCUSSION.

DR. A. J. OCHSNER, Chicago, emphasized that adenoids are constantly exposed to the absorption of septic material.

DR. J. F. BARNHILL said he believed that affections of the stomach arise from catarrhal discharges caused by adenoids. When it is realized that the greatest per cent. of all ear diseases is due to adenoids alone, from a causal standpoint it is very important to remove the cause.

The Diagnosis and Operation for Gallstones.

DR. W. D. HAGGARD, Nashville, Tenn., in this paper, said that the most valuable local sign is hypersensitiveness under the tip of the ninth costal cartilage. Stones in the gall bladder without inflammatory or other complications are never attended by enlargement, and empyema is also characterized by tumefaction. Stones in the gall bladder without inflammatory or other complications are never attended by enlargement, and an enlarged gall bladder means there is no stone in the common duct, as enunciated by Courvoisier. This is a most valuable differential sign. In biliary obstruction manifested by chronic jaundice, an enlarged gall bladder means that the obstruction is not due to a stone. Gallstones and certain stomach, appendix or kidney lesions may coexist. The technic of various operations was described.

DISCUSSION.

DR. H. H. GRANT said that exploration was justifiable whenever disease of the gall bladder was reasonably probable. It is more prudent to explore than to allow serious complications to arise.

DR. LEWIS S. MCMURTRY narrated a case to illustrate that there might be stones in the common duct without any jaundice, and, also, that in some of these operations there is danger of death from the inflammatory changes that have taken place.

DR. A. H. CORDIER said that where the stones are in the common duct, regardless of whether there was jaundice or not, the pain is very much nearer the median line than when they are in the cystic duct or in the gall bladder.

The Prophylaxis of Tetanus.

DR. S. C. STANTON, Chicago, contributed a valuable statistical paper, calling attention to the investigations of THE JOURNAL of the American Medical Association on this important subject. He recommended prophylaxis under five heads: 1. The enforcement of existing laws regarding the sale of toy pistols and other dangerous toys. 2. The enactment of laws by Congress, state legislatures and municipalities prohibiting the manufacture and sale of toy pistols, blank cartridges, dynamite canes and caps, cannon crackers, etc. 3. The open treatment of all wounds, however insignificant, in which, from the nature or surroundings, there is any risk of tetanus. 4. The immediate use of tetanus antitoxin in all cases of Fourth-of-July wounds, wounds received in barnyards, gardens, or other places where the tetanus bacillus is likely to be present or tetanus infection to occur. 5. The injection of tetanus antitoxin as soon as tetanic symptoms become manifest.

The association took action on the paper, endorsing the above recommendations and instructing the secretary to send the recommendations and the association's action thereon to the medical press, the Associated Press, and the various state medical societies, asking that they take action thereon.

Indications and Technic of Prostatectomy.

DR. G. FRANK LYDSTON, Chicago, pointed out that the senile prostate was an atrophied prostate. Catheter life lasts about five years. In prostatic hypertrophy, he believes the tumor to be purely adenomatous at the outset. He had no hesitation in saying that early operations on the prostate in otherwise healthy subjects are no more dangerous than interval operations for appendicitis. The perineal operation should be performed whenever practicable, but he was aware that there were cases which could not be dealt with sucessfully by this route; therefore, it might become necessary to do a combined perineal and suprapubic operation.

Surgery of Pulmonary Gangrene.

DR. L. L. MCARTHUR, Chicago, after reporting cases, presented these conclusions:

1. Since by medical treatment 80 per cent. of patients die and in those operated on about 29 per cent., efforts should be surgical.
2. While it is anatomically possible to separate the pleura from the chest wall, it is tedious, difficult and often futile (due to puncture), and, therefore, not much valuable time should be lost in such efforts.
3. Circular suture, combined with gauze pressure packing for forty-eight hours, is the best means of inducing adhesions.
4. The *x*-ray may give valuable aid in localization.
5. Great care should be used in the selection of cases for operation, but when localized and single, the most desperate cases should be given a chance, as they frequently recover with drainage.

The Present Status of Stomach Surgery.

DR. A. J. OCHSNER, Chicago, in this valuable paper, discussed the various conditions in detail, and concluded that if severe pathologic conditions of the stomach exist, which can not be relieved medically in a reasonable period of time, and which can neither be traced satisfactorily to a neurosis not secondary to gastric disease, nor to other conditions, it would seem proper to attempt relief by early surgical treatment.

Among the other papers read were the following:

"The Perfected Surgical Treatment of Fibroid Tumors of the Uterus," by Dr. Lewis S. McMurtry, Louisville, Ky. "Changes in the Gullet Wall Following the Destructive Action of Escharotics," by Dr. Joseph Rilus Eastman, Indianapolis. "Extrauterine Pregnancy," by Dr. A. H. Cordier, Kansas City, Mo. "The X-ray in Fractures," by Dr. Duncan Eve, Nashville, Tenn. "Treatment of Compound Fractures, Immediate and Remote," by Dr. Frederic A. Besley, Chicago. "Ectopic Gestation," by Dr. Anderson Watkins, Little Rock, Ark. Dr. A. R. Craig, Columbia, Pa., reported cases of gunshot wounds; Drs. Bransford Lewis, St. Louis, and W. N. Wishard, Indianapolis, showed instruments, and Dr. H. J. Whitacre, Cincinnati, discussed "The Pathology and Treatment of Gangrene of the Lower Extremities."

CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA.

Eighteenth Annual Meeting, held in Baltimore, Oct. 23 and 24, 1903.

The vice-president, Dr. John Guiteras, Havana, in the Chair.

A welcome was extended by Dr. Eugene F. Cordell, president of the Medical and Chirurgical Faculty of Maryland and by Dr. William H. Welch, president of the Maryland State Board of Health.

Reports were presented on the following subjects: Rules Governing the Transportation of the Dead; Promotion of Uniformity of Reports on Vital Statistics; Work of the Maryland State Tuberculosis Commission. About 30 attended the conference.

New Officers.

The following were elected officers for the ensuing year: President, John M. Hurty, M.D., Indiana; secretary, Gardner T. Swarts, M.D., Rhode Island; treasurer, J. A. Egan, M.D., Illinois; vice-president, John S. Fulton, M.D., Maryland.

Papers were read as follows: 1, "Etiology and Prevention of Infantile Diarrhea," by Dr. J. H. Mason Knox, Baltimore; 2, "Are the Laboratory Methods of Diagnosis in Infantile Diarrhea Applicable in Public Health Work?" by Mr. Edwin G. Shorer, Baltimore; 3,"Duty of Sanitarians Regarding Venereal Diseases," by Dr. Henry D. Holton, Brattleboro, Vt.; 4, "Another Year's Test of the Mosquito Doctrine of the Transmission of Yellow Fever in Havana," by Dr. John Guiteras, Havana.

Yellow Fever and Mosquitoes.

Dr. Guiteras reported that in over two years there had not been a single indigenous case of yellow fever in Havana. During the last year there were 8 cases admitted to Las Animas Hospital, all coming from Mexico; one of those died on the third day. There were 131 non-immune patients in the same institution during the same period, but the disease was absolutely controlled by isolation, wire screens, mosquito nets and destruction of the mosquitoes by burning pyrethrum powder in the rooms. The fatal case showed the value of these measures very strikingly. A man was over two days in the lower part of the city, the former focus of infection, before he went to the hospital. During this time he was bitten by mosquitoes repeatedly, yet by the destruction of these in the house where he had been and in the houses of the entire square, the spread was entirely prevented. Dr. Guiteras detailed the prophylactic methods, which are familiar to our readers.

The people of Havana have implicit confidence in the measures employed there, which can be readily carried out. The presence of a case of yellow fever creates no alarm. In one of the 9 cases, a patient coming on the steamer from Mexico was forcibly removed from it against the wishes of the captain, because the authorities of Havana knew they could deal effectually with it and feared if it were permitted to remain the vessel might become infected before reaching New York or the disease might get a foothold in that city.

Venereal Prophylaxis by Health Boards.

As a result of Dr. Holton's paper a committee was appointed in accordance with the following resolution, which was proposed by Dr. Probst and adopted by the conference:

Whereas, The great prevalence of venereal diseases, which is indirectly the cause of many deaths, is a matter of much concern to the public health; and,

Whereas, The communication of these diseases to innocent persons must be largely due to ignorance; be it

Resolved, That a committee of three be appointed by the president to prepare a leaflet that would be acceptable to physicians to give to their patients, setting forth the precautions to be taken by one suffering from a venereal disease to prevent its communication to others, and to make such other suggestions as it may deem proper. Such instructions, when adopted by this conference, to be recommended to state and provincial boards of health for dissemination among the medical profession, and said committee shall report at the next meeting.

National rules to govern the transportation of the dead were adopted.

The Etiology and Prevention of Infantile Diarrhea.

Dr. John H. Mason Knox, Baltimore, in the paper mentioned above, said that the pathogenicity of the *Bacillus dysenteriæ* was now well established. In his own investigations no one type of the disease was associated with this organism; but all types of intestinal diseases, common among children in summer, were caused by the same organism. Laboratory investigation had shown two or three types of organism very closely related. Cases also occurred in winter. He emphasized the importance of supplying the children of our large cities with pure milk and uncontaminated water.

Mr. Edwin G. Schorer, Baltimore, in his paper, said that with the establishment of the etiology of infantile diarrhea a great step in advance had been made, yet, under the present conditions, methods of diagnosis are not available for, or applicable to, public health work. This last statement may, however, be limited, inasmuch as a bacteriologic diagnosis will undoubtedly be of value in the limited number of persistent cases of diarrhea and in those in which the antidysenteric serum is to be given.

DISCUSSION.

Dr. William H. Welch, Baltimore, was surprised that Dr. Knox had found the organism, which had been proven to be the cause of a prevalent group of cases of dysentery, to be the cause of summer diarrheas of children. The organism must be found in other localities than Maryland in order to demonstrate that it has any causal relation to summer diarrhea of children.

Dr. Henry M. Bracken, Minneapolis, discussed the milk question, recommending certified milk when an artificial diet is necessary for children. More infants die every year, he said, from impure milk than from tuberculous milk. More attention should be given to the sanitary aspects of the dairy than to the diseased animal. Certified milk and pasteurized milk are as satisfactory articles of diet as can now be obtained.

Dr. Charles O. Probst, Columbus, Ohio, considered it very important to disinfect the stools in infantile diarrhea.

Mr. Frank Wells, Lansing, Mich., said the Michigan State Board of Health had published a leaflet on the subject of infantile diarrhea, which had been given wide circulation and which advised that all cow's milk given to infants should be pasteurized. The leaflet was furnished to all of the teachers of public schools in Michigan. It was the duty of boards of health, he thought, to furnish such information to the people.

Dr. Henry Mitchell, Asbury Park, N. J., urged repeated inspections of cases of diarrhea in both children and adults, as in cases of typhoid fever. The New Jersey legislature had given the State Board of Health authority to make such inspections.

Others discussed the subject and Dr. Knox, in closing the discussion, agreed with Dr. Probst that the disinfection of stools in infantile diarrhea is as essential as in typhoid fever. In answer to one of the questions asked, Dr. Welch said the Shiga organism was not present in normal stools. If it were, it was in such small numbers that it required the most painstaking investigation to find it.

NEW YORK STATE MEDICAL ASSOCIATION.

Twentieth Annual Meeting, held in New York City Oct. 19-22, 1903.

The president, Dr. F. H. Wiggin, New York, in the Chair.

The New Officers.

The following officers were elected: President, Dr. William H. Thornton, Buffalo; vice-president, Dr. Charles S. Payne, Liberty; secretary, Dr. Guy D. Lombard, New York; treasurer, Dr. Frederick A. Baldwin, New York; delegates, Drs. Joseph W. Grosvenor, Buffalo, and E. Eliot Harris, New York.

It was announced that during the past year 14 new county medical associations had been added, and 372 persons added to the list of active members. The present membership is 1,757.

The association adopted the Kyger resolutions (which have been printed in The Journal) which call attention to the lessened birth rate among Americans and urge the prohibition of the publication of abortion advertisements. There were also adopted the American Medical Association resolutions on the examination of the eyes of school children. The association voted to continue the endeavor to have the office of coroner abolished.

Stab Wounds of the Abdomen.

Dr. F. J. Douglas, Utica, read this paper, emphasizing the uncertainty of the symptomatology and the consequent necessity for prompt exploratory laparotomy. Probing was strongly condemned. After suturing any wounds of the viscera, the cavity should be flushed out, and the wound closed, usually without drainage.

The Relation of the Municipal Milk Supply to the Health of Children.

Dr. George W. Goler, Rochester, compared mortality statistics of that city for the two periods, 1891-96 and 1897-1902, i. e., the periods before and after the adoption of a bacterial standard of purity, and a systematic attempt to secure cleaner milk. This showed a reduction in mortality during the latter period of 65 per cent. for infants during the first year of life, and of 58 per cent. for children between one and five years of age. For the past four years the city of Rochester had endeavored to make the city milk conform to a standard of 100,000 bacteria per c.c. Just before this standard was made 27 per cent. of the samples analyzed showed an average of 837,000 bacteria; whereas just after this time 391 samples averaged 796,000 bacteria and 15 per cent. of the samples contained over five million per c.c. In 1901 the average was 275,000 bacteria, with 9 per cent. of the samples showing over five million bacteria. In 1902 the average was 215,000, 74 per

cent. of the samples coming within the standard and only 6 per cent. showing over five million. Since 1897 milk stations had been established during the summer for the purpose of supplying at cost clean milk for infants. Last summer this milk showed only 14,000 bacteria as against 235,000 bacteria per c.c. for the ordinary city milk on the same days.

DR. H. O. MARCY, Boston, described a method of refrigerating and condensing milk that had been in operation in New Hampshire for six years. Milk so treated would keep sweet for two weeks. He confidently expected it would revolutionize the milk business.

The Causes of Failure After Operation for Nephroptosis.

DR. AUGUSTIN H. GOELET, New York, read this paper. Among some of the causes enumerated were the following: (1) Delay in operating until the patient's condition was bad and the kidney disabled; (2) the existence of severe enteroptosis; (3) the neglect to so prepare the patient as to minimize retching and vomiting after operation; (4) incomplete detachment of the colon; (5) penetration of the structure of the kidney by sutures; (6) attachment of the kidney so low down as to expose it to the pressure of the corset; (7) to early removal of the sutures; (8) prolonged retention of the gauze drain; (9) allowing the patient to turn on the opposite side or to assume the erect position too soon; (10) the neglect to apply a proper support to the abdomen afterward or the too early use of the corset.

Ergot in Alcoholism and Morphinism, and the General Class of Drug Habit Cases.

DR. ALFRED T. LIVINGSTON, Jamestown, read this paper. He believed that the nervous disturbances experienced by these patients were the result of a disturbance of the vascular system, and that the restoration of the equilibrium of the circulation should be the object of treatment. This can be brought about in several ways, but the most certain and potent is by the hypodermic administration of ergot. This drug not only contracts the muscular coat of the blood vessels, but the degree of action is proportionate to the relaxation of those muscular fibers. The first step in the treatment of a drug habit is, of course, to wholly stop the use of the drug; the next is to give a purgative and begin the use of ergot. The bowels should be kept relaxed, preferably by giving one or two drams of the fluid extract of *Rhamnus frangula* from one to three times a day. Ordinarily, two or three injections of half a dram each of his 12.5 per cent. solution of ergot will be enough per diem, but occasionally it will be necessary to give it every two hours. (See formula, etc., in THE JOURNAL, March 21, 1903, page 774). He had never had a patient request the drug, or show any desire for it after the first forty-eight hours. In the very severe forms of the morphin or opium habit it was occasionally better to give, with the ergot, a fraction of the former daily dose of the drug, reducing the dose of the narcotic one-half each day until it is wholly stopped by the eighth day. In the treatment of these difficult cases the use of hypnotics should be avoided if possible. If they seemed to be urgently indicated, rather than give them he would resort to the use of galvanism. A current of 10 or 15 milliamperes should be employed, and should be applied to the cervical ganglia and, by stroking motions, to the whole length of the spine, holding the electrodes about five inches apart.

DISCUSSION.

DR. ALEXANDER LAMBERT, New York, spoke of his experience with the ergot treatment in the alcoholic wards of Bellevue Hospital. An experience of a number of years showed that in his service of six weeks there were usually 25 or 30 deaths under all the generally accepted methods of treatment, and that in the cases known as "wet brains" he could not save more than 3 per cent. Since the adoption of the ergot treatment his six weeks' service had yielded, on an average, only 6 or 7 deaths, and, most remarkable of all, he had only lost 2 out of 30 cases of wet brain. His method was to inject 30 minims of the solution of ergot, repeat this in one hour, and then give it at intervals of two hours. When a patient was disposed to be violent or greatly excited the first injection contained, also, a dose of apomorphin, as this produced an almost immediate calming effect.

DR. F. H. WIGGIN also spoke favorably of the use of ergot in delirium tremens and obstinate insomnia, but said he had found it necessary to use doses of 50 or 60 minims.

Results of Operative Treatment of Cancer of the Rectum.

DR. JAMES P. TUTTLE, New York, read this paper and exhibited some patients. He gave the results obtained by him in 43 excisions, and asserted that no other method than extirpation had ever cured a single case of carcinoma of the rectum or sigmoid. Colostomy was the only operation that could be compared with it, and his belief was that colostomy did not prolong life and was only indicated when scirrhous growths completely occluded the gut, or the growth was of the hemorrhagic type. Extirpation gave complete relief and buoyed up the patient with the possibility of a cure. Of the 43 cases, 12 were unsuccessful; 22 are now living and well, after periods of from 2 to 11 years. The speaker said that every case of diarrhea, with or without bloody discharges, lasting over a fortnight should be subjected to an instrumental examination of the rectum or colon. A failure to make an early diagnosis is the greatest cause of death, and next to it came infection, but very often the latter could not be avoided. A carcinoma that was not movable was usually considered inoperable, but he had several seemingly hopeless cases that he had been tempted to operate on by the earnest entreaties of the patient, and the fact that every now and then life could be spared and the person restored to usefulness and comfort should make the surgeon chary about absolutely refusing to operate even though the chances of benefit were slight.

One of the Dangers in the Surgery of the Biliary Passages.

DR. E. D. FERGUSON, Troy, said that the surgeon should endeavor to secure a symptomatic cure rather than to do an ideal operation. The operation which gives the least shock is usually the formation of a temporary biliary fistula after the removal of the gallstones.

Extradural Abscess and Mastoid Disease.

DR. SEYMOUR OPPENHEIMER, New York, said that epidural abscess was the most frequent intracranial complication of mastoid disease, yet the early symptoms afford no basis for proper differentiation. Pain in the head over the affected area is an important symptom, which is apt to be paroxysmal and associated with exquisite tenderness. If rigors are present there is reason to suspect sinus involvement.

DR. FRANK W. HIGGINS, Cortland, suggested that in exploring the brain for pus accumulations it would be helpful to remember that these abscesses were three times more frequent in the middle than in the posterior fossa.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Toxic Actions of Urotropin.

The toxic action of urotropin, as described by Coleman in *Med. News*, is shown in some individuals, even though given in small doses. The symptoms of toxicity shown are irritation of the stomach; diarrhea and abdominal pain; measles-like rash; headache and ringing in the ears; renal irritation sometimes accompanied by albuminuria. The bladder sometimes presents toxic effects, strangury being the most common symptom. Hematuria and hemoglobinuria may occur. The toxic symptoms generally disappear within a few days after the drug is withdrawn. The author concludes that these toxic symptoms are caused either from special susceptibility to the action of the formaldehyd or to interference with its elimination or to an unusual liberation of formaldehyd in the system.

Cystitis.

There is an advantage, according to the *Jour. de Med. de Paris*, in prescribing salol internally in the form of an emulsion instead of powder form in the treatment of cystitis. The following formula is recommended:

℞.	Salol	gr. xxx-3i	2-4 |
	Pulv. tragacanthæ	gr. ii	|12
	Pulv. acaciæ	gr. xxx	2 |
	Tinct. tolutani	3i	4 |
	Syr. simp.	℥ss	15 |
	Aq. destil. q. s. ad	℥ii	60|

M. Sig.: Ft. emulsio. Sig.: One teaspoonful before each meal.

The following combinations are recommended by *Merck's Archives* in the treatment of cystitis:

To relieve the pain:

℞.	Ext. opii	gr. vi	|40
	Ext. hyoscyami	gr. v	|30
	Olei theobrom. q. s.		|

M. Ft. suppos. No. vi. Sig.: One to be introduced into the rectum at night; or:

℞.	Pulv. opii	gr. xii	|75
	Camphoræ	℥ss	2 |
	Ext. belladonnæ	gr. iii	|20
	Olei theobrom. q. s.		|

M. Ft. suppos. No. vi. Sig.: One to be inserted at bedtime.

As an antiseptic and to relieve the irritation the following is of service:

℞.	Ext. belladonnæ flu.	gtt. xx	1|30
	Sodii boratis	3ii	8 |
	Acidi benzoici	gr. xx	1|30
	Tinct. opii camph.	℥iss	45|
	Olei gaultheriæ	gtt. xii	|75
	Syrupi	℥ii	60 |
	Aq. destil.	℥iv	120|

M. Sig.: One dessertspoonful in water four times a day.

Acute Gastro-Enteritis of Nurslings.

There are three therapeutic indications according to Hutinel in *Interstate Med. Jour.*, for the treatment of acute gastro-enteritis occurring in infants:

1. To remove the source of the poisons which form in the intestine.

2. To prevent the pathogenic germs in the intestinal tract from finding a favorable culture medium.

3. To restore to the body the water it has lost.

He states that all the foregoing conditions can best be met by the withdrawal of all food and giving sterile water alone. When there is much tendency to vomit the water should be given cold; if there be algidity, hot water should be used, in either case giving small quantities at a time—a dessertspoonful or a tablespoonful every fifteen or twenty minutes. For infants five or six months old the total quantity should not exceed one and a half pints in the twenty-four hours. This treatment must not continue longer than twelve to fifteen hours, for a young infant, if any improvement is shown; for older children it may be continued twice that long. Gastric lavage is indicated when there is persistent vomiting, and if thrush is present a mild alkali may be added to the lavage water. The writer relies entirely on small and repeated doses of calomel for intestinal antisepsis. Castor oil may be used if the stomach is not too irritable.

Colonic flushings are sometimes valuable, using mucilaginous solutions or the normal saline solutions, never using boric acid on account of its toxic effects on infants. Warm cataplasms should be applied to relieve the tympanites.

Where there is tendency to collapse hypodermoclysis of salt solutions should be given.

Warm baths are of value in reducing the hyperpyrexia. The return to food must be gradual, using diluted milk, buttermilk or koumyss with the addition of flour.

Treatment of Stye.

According to an abstract in *Med. Record* the lash should be removed from the center of the inflammatory area. The swelling should be carefully touched with tincture of iodin or pure carbolic acid. When pus is present it should be released by a small incision. The pain will be relieved by warm fomentations. A weak mercurial ointment will generally cause the disappearance of the remaining thickening of tissue. The diet should be regulated when there is any constitutional disturbance.

To Relieve the Cough in Pneumonia.

The following combinations are recommended by Text-Book of Applied Ther. in the treatment of the cough in pneumonia:

℞.	Codeinæ	gr. i	|06
	Quininæ sulph.		
	Pulv. camphoræ, āā	gr. xvi	1|06

M. Ft. cap. No. viii. Sig.: One every three hours; or:

℞.	Ammon. carb.	3i	4 |
	Syr. pulveris doveri	3iv	15|
	Syr. pruni virg.	℥iss	45|

M. Sig.: One teaspoonful every two or three hours.

Lichen Pilaris.

The following combinations have been recommended by *N. Y. Med. Jour.* in the treatment of lichen pilaris:

℞.	Sulphuris precip.		|
	Fuller's earth		|
	Venetian talci, āā	gr. lxxv	5|

M. Ft. chartula. Sig.: Apply as required.

The following have been successfully used by Saalfelt:

℞.	Sulphuris precip.	3iiiss	14|
	Saponis mollis		|
	Adipis, āā	℥i	30|
	Venetian talci	3iv	15|

M. Sig.: Apply locally; or:

℞.	Saponis mollis	℥iss	45|
	Naphthol	3iiiss	14|
	Cretæ prep.	3iiss	10|
	Lanolini		|
	Adipis, āā	℥iss	45|

M. Sig.: To be used at night.

Brocq recommends the following:

℞.	Amyli glyceriti (neutral)	℥iiiss	105|
	Acidi tartarici	gr. lxxv	5|

M. Ft. lotio. Sig.: Apply locally. For the immediate treatment of these cases Hyde recommends the hot bath with soap followed by inunctions of lanolin pomades, or the fats or oils. In congenital types cod-liver oil should be given internally.

Sweating of the Feet.

The following combinations are recommended by *Merck's Archives* in excessive perspiration of the feet:

℞.	Acidi salicylici	gr. xv	1|
	Tannoformi	℥iss	6|
	Pulv. orris	3i	4|
	Pulv. talci	3iii	12|

M. Ft. pulvis. Sig.: Apply locally; or:

℞.	Formaldehyde	3iv	15|
	Petrolati	3ii	8|
	Lanolini	3iv	15|

M. Ft. unguentum. Sig.: Apply freely at night; or:

℞.	Pulv. acidi borici	3i	4|
	Pulv. amyli	3iii	12|
	Tannoformi	3ii	8|
	Olei caryoph.	gtt. i	|06
	Olei lavendulæ	gtt. iii	|20

M. Sig.: Use as a dusting powder.

In axillary bromidrosis the following is recommended:

℞.	Creolini	3i	4|
	Ext. violet	3iv	15|
	Alcoholis deod.	℥iii	90|

M. Sig.: Wash the armpits with warm water followed by an application of the lotion.

Uranium Nitrate in Diabetes.

There is no disorder of the system in which empyricism has assumed a more important place in therapeutics than in the treatment of diabetes mellitus. W. R. Jones, in *Virginia Semi-Monthly*, states that he derived splendid results from the use of uranium nitrate in the treatment of this disorder of metabolism. In every case in which this preparation has

been used by the author great improvement has resulted. It should be given in doses of gr. 1/6 (.01) to gr. ½ (.03) four times a day, administered in water, alcohol or glycerin. The salts of uranium, while not luminous, are strongly fluorescent, which, according to the writer, lends interest because of the discussion of radium at the present time. But whether the fluorescent property in any way affects metabolism can not be stated. He refers to the action of uranium on the skin producing a fine desquamation of the superficial layers of the epidermis somewhat similar to the effect of the *x*-ray. The degree, however, is very moderate and gradual. The general nutrition and activity of the skin is increased as well as the diaphoretic action, so that it is recommended for its beneficial effects on metabolism.

It is a yellowish-green, crystalline solid, soluble in water, alcohol, ether and glycerin. Some authors give it in 1 to 2 gr. (.06-.12) doses.

[The value of this preparation in diabetes because of its amylolytic and proteolytic action has been discussed by Dr. Samuel West. He employed it in the treatment of diabetes. It relieved the subjective symptoms and reduced the amount of sugar.]

Arsenic is a well-tried remedy in the treatment of diabetes and experiments have proved its value in reducing the formation of glycogen. The bromid of arsenic may be given made up as follows after the formula of Clemens:

℞. Potassii carb.
Acidi arsenosi ..... gr. vi | 40
Aquæ destil. ..... ʒi 30 |

M. Boil until dissolved and when cooled add:

Aquam q. s. ad..... ʒiss 45|
Bromum ..... gr. xii |75

M. Sig.: One to five drops once or twice daily.

The following formulæ are often of value in reducing the quantity of sugar in the urine:

℞. Lithii carb. ..... 3i 4|
Sodii arsenatis ..... gr. i |06
Ext. cascaræ ..... gr. xv 1|

M. Ft. capsulæ No. xxx. Sig.: One after each meal.

Uranium nitrate may be prescribed in solution as follows:

℞. Uranii nitratis ..... gr. xv-xxx 1-2|
Syrupi simplicis ..... ʒi 30|
Aquæ folniculi ..... ʒiii 90|

M. Sig.: One teaspoonful after each meal three times a day.

Codein is another preparation which is used as much, perhaps, in the treatment of diabetes as any other drug. This may be of service not only because it favorably influences the sugar elimination, but it also alleviates, to some extent, the pains which so frequently accompany this condition. It may be given as follows:

℞. Codeinæ sulph. ..... gr. viiss-xv |50-1.
Syr. simplicis ..... ʒss 15|
Aq. aurantii q. s. ad. ..... ʒii 60|

M. Sig.: One teaspoonful three times a day.

Medicolegal.

SOME LEGISLATION OF THE YEAR 1903.

Idaho—Physicians to Report and Quarantine.—Section 1152 of the political code of Idaho as set forth in the revised statutes is amended by an act on pages 364 and 365 of the Idaho Session Laws of 1903 so as to read: It is the duty of every practicing physician to report promptly to the county physician of the county in which he resides, all or any dangerous disease of an infectious or contagious nature under treatment by him, and he is also hereby empowered and required to at once establish a strict quarantine against such person or premises by such means as shall seem to him to be sufficient, subject to revision by the county board of health, and said board must at once take the necessary precaution to prevent the spread of such dangerous or infectious disease, and any person violating the provisions of this act, or the regulations of said attending physician, or of the county board of health, is guilty of a misdemeanor.

Indiana—Creation of Anatomical Board.—Chapter XXXI of the Acts of Indiana of 1903 provides for the creation of a board for the control and distribution of the unclaimed bodies of persons dying in public institutions of, or charitable institutions aided by, the state, and which would otherwise be required to be buried at public expense or at the expense of such public institutions. The board is to be known as the state anatomical board and is to consist of the president of the State Board of Health, ex-officio, who shall act as the chairman, and one representative from each of the incorporated medical and dental schools of the state actually engaged in teaching, to be selected by and from the faculty thereof. Exceptions are made as to the bodies of persons dying with smallpox, diphtheria or scarlet fever, and to those of travelers dying suddenly, except those belonging to the class commonly known as tramps. The board or its agent may receive the bodies and shall distribute such as are received among such schools and physicians entitled thereto as request in writing to receive the same, preference being given to the incorporated schools. Each college shall receive annually, as nearly as may be practicable, such proportion of the entire number of bodies distributed as the number of bona fide students enrolled and in regular attendance at such school shall bear to the total number of bona fide students at all such colleges. All bodies shall be delivered in regular order so as to maintain an equitable allotment; and bodies assigned to any school in regular order and refused by it without sufficient cause shall be charged against its quota. No school or physician shall receive any body without first giving to the state a bond for $1,000, conditioned that all such bodies received shall be used only for the promotion of the science and art of medicine and of dentistry, and that the record containing descriptions of deceased bodies shall be preserved from loss. Nothing in this act shall be construed to prevent any duly incorporated medical or dental college, or any duly licensed practitioner from acquiring, by gift or otherwise, from persons having lawful authority to dispose of the same, the dead body of any human being for the purpose of postmortem examinations, dissection or other scientific use. But desecrating graves, trafficking in bodies referred to herein or in bodies known to have been unlawfully taken is made a felony, punishable by imprisonment for not less than three nor more than ten years.

Indiana—To Restrict Dangerous Communicable Diseases.—Chapter LXXXIII of the Acts of Indiana of 1903 provides that any physician called on to attend a sick person and who finds the cause of such sickness to be of a contagious or infectious character, or if the disease is ordered to be reported in the rules of the State Board of Health, such physician shall immediately report the facts to the secretary of the board of health having jurisdiction. Whenever any person knows, or has reason to believe, that any member of his (or her) family or household (boarder, roomer or visitor) has any communicable disease listed in the rules of the State Board of Health, he shall immediately, if no physician is in attendance, give notice to the local health officer. The health officer being notified in any way of the existence of any of said diseases shall immediately quarantine the infected premises so as effectually to isolate the case or cases and the family, if necessary, in such manner and for such time as may be necessary to prevent transmission of the disease; and, whenever a house or room is placed in quarantine, a placard shall be posted in a conspicuous position, giving the name of the disease in letters not less than two inches long, and also containing the following order: "All persons are forbidden to enter or leave these premises without special permit from the health officer having jurisdiction, and all persons are forbidden to remove or mutilate this card, or to in any way interfere with this quarantine without orders from said health officer." When visiting persons afflicted with such infectious disease, all physicians and health officers shall take precautions as directed in said rules. Other provisions make it the duty of the health officer to investigate, etc., whenever he knows or suspects or is informed

of the existence of a communicable disease, dangerous to the public health, and to disinfect the premises, etc., after the recovery or death of infected persons. After examination and determination by two physicians in good standing and practice that a person is sick with a contagious, infectious or pestilential disease, the state or local board of health may cause such person to be removed to a proper place for care, and may cause to be removed or destroyed articles infected or likely to communicate disease, when in their opinion the safety of the public health requires it. Children infected with, or having been exposed to any communicable disease shall not attend any school, or appear in public in any way, and all school teachers shall exclude all such children unless a written permit to attend is given by the health officer. In all cases of death from cholera, bubonic plague, leprosy, typhus fever, yellow fever, smallpox, diphtheria, membranous croup, scarlet fever, and cerebrospinal meningitis, the funeral shall be strictly private, and the burial shall be made within twenty-four hours after death. No public or church funeral shall be held or any person permitted to enter the house containing the remains, except the undertaker and his assistants, unless by permission of the health officer, and buried remains shall not be disinterred or removed without permission from the State Board of Health. All trolley, steam or electric cars or other public conveyances which are known, or which may reasonably be supposed to contain the infection of any disease, shall, on order of the health officer of that jurisdiction, be disinfected according to the rules of the State Board of Health, and the cost of disinfection shall be paid by the owner of said cars or conveyance: provided, that any and all inspections and fumigations of such cars be at such times and places as not to interfere with the general traffic of the road. If at any time any city, town or region is under quarantine, all trolley, electric and steam railroad companies through any such quarantined city, town or region, shall obey the quarantine orders of the State Board of Health, which are issued for the purpose of preventing the spread of infection.

1.—See Society Proceedings, this issue.

2. **Potassium Sodium Tartrate.**—This paper by Kleeberg gives the results of experimental research on the action and circulation of potassium sodium tartrate. The apparatus employed was the kymograph of Ludwig. Dogs were used for the experiments, in each case the animal receiving an injection of ¼ grain of morphin sulphate half to three-quarters of an hour before the beginning of the administration of ether. The cannula was invariably introduced into the carotid artery and the salt injected into one of the crural veins. The results are summarized as follows:

1. Potassium sodium tartrate when introduced intravenously in small amounts (up to 30.0 mg. per kilogram of dog) causes a fall in blood pressure and an irregularity in the rhythm of the heart's action. This may be accompanied by a primary slowing of the heart's beat, but the dominant action is to cause an increase in the rate of pulsation. The fall in pressure occurs even though the quantity of salt injected contains less than 3 mg. of potassium per kilogram of dog. If the amount introduced is larger and yet insufficient to cause complete paralysis of the heart, the fall in blood pressure is accompanied by a slowing of the heart. If the salt is introduced in comparatively large quantities, the animal quickly expires, owing to paralysis of the heart, respirations continuing for some moments after the heart has been arrested in diastole.

2. Neutral sodium tartrate when introduced intravenously in moderate amounts (about 50 mg. per kilogram) stimulates the heart, causing a rise in blood pressure, with a slight increase in heart rate.

3. The depressing factor is the potassium ion, and the sodium and tartaric acid ions are without influence in causing the depression.

3. **Diabetes.**—The predominant symptom of diabetes, glycosuria, may, Butler says, be the expression of many other diseases; sometimes it is only the result of an excess of carbohydrates. He enumerates a number of conditions in which glycosuria may occur, such as neuroses, insanity, autotoxic types of gout and mental disorder. He reviews the various neurotic manifestations which may attend the diabetes and the motor and sensory lesions in trophic disorders. Among the former are fatigue, lassitude, monoplegias, imperfect coordination, vertigo, etc. The most serious symptom is coma. There are included under this title many conditions varying from mental depression through apathy to stuporous states. In nearly all, the mental features and the concomitants of coma center, like all depressional mental states from acidosis, around the medulla oblongata. Their starting point is central not local. The condition of the arteries also is a factor in the etiology of glycosuria. Hereditary defect may show itself at the periods of stress, the change from infancy to childhood, puberty, adolescence, the climacteric and the period of senility, when the system is undergoing evolution or involution.

4. **Influenza.**—Wood notices the various organic and functional disorders of the heart attending influenza, and says in conclusion that study and observation force him to believe that influenza is a potent and not uncommon factor in the production of serious cardiac disease, and that there are frequently degenerative changes in the heart wall. In weakened subjects or elderly persons these changes may lead to grave symptoms. In view of the dangers of cardiac complications, the routine treatment of the disease with drugs like phenacetin, acetanilid, etc., can not be too strongly condemned, certainly not in patients past middle life.

5. **Tuberculosis.**—Dunn holds that the value of percussion or auscultation findings and of symptoms is dependent on the recognition of the limitation of their significance. The temperature is a guide only with frequent regular observations, and an auscultation chart made while listening to the sounds is an essential aid to accuracy of both observation and record. Negative sputum findings are never sufficient ground for negative diagnosis, and blood examinations aid only in the incipiency of the disease except in excluding the conditions in which the blood findings are characteristic. The significance and reliability of agglutination are not yet fully established. The tuberculin test is a safe, reliable, practical and justifiable diagnostic measure where its use is indicated; that is, in suspected early cases where other means of diagnosis have failed. When a positive diagnosis can be made without its use it should be condemned as a meddlesome procedure. He notices, however, in regard to the use of tuberculin one peculiar reaction he has observed three times: a fall of temperature to subnormal, a feeling of general weariness and depression, aching not marked or absent and local reaction more or less marked. He can not explain the phenomenon. He did not care to give a second larger dose just to see whether a rise of temperature could be produced, but does not believe that these cases should be confused with the unfortunate case reported by Heron at the British Congress on Tuberculosis.

6. **Antistreptococcic Serum in Rheumatism.**—A number of cases are reported by Sherman, showing the therapeutic value of antistreptococcic serum, 2 of erysipelas, 1 of miscarriage and 9 cases of rheumatism. In all his rheumatic cases there was a typical clinical history of inflammatory rheumatism with early evidences of more than usual severity in certain ones. All the patients had good digestion. None developed heart complications, and while the serum treatment was used no other treatment was resorted to. The results varied from marked improvement after the first or second dose to complete recovery in a short time. The local effects of the injections were not serious. He thinks that antistreptococcic serum

might also benefit muscular, sciatic and chronic articular rheumatism. At least a trial would do no harm and might lead to good results.

8. Bronchiectasis in Tuberculosis.—Hoffmann's suggestion that bronchiectasis can not occur as a complication of tuberculosis is commented on by Solly, who reports a case which in its way is exceptional. He has found no record of a similar one. The patient was a woman subject to frequent attacks of bronchitis with periods in which there was a great deal of spasmodic coughing without expectoration, depression of health, but no fever and then a continuous fever, not intermittent, cough diminished, still no expectoration, emaciation, general depression, gastro-intestinal indigestion and no relief of the fever from treatment. Then a rapid increase in the temperature with bacilli first appearing. With the administration of iodid of potassium, which seemed to cause an absorption of lymph and the free escape of tuberculous matter, there remained an ordinary mild hectic fever with free expectoration and moderate cough, with occasional exacerbations of the high, continued fever which existed before, again relieved by the iodids. Finally, a period of six weeks of almost steady improvement with free but slightly diminishing cough and expectoration. Locally there was an old inactive tuberculous process at the right apex and solidification around the root of the right lung with slight incomplete atelectasis of the right lower lobe. Following the attack these two conditions were diminished with some return of activity at the extreme right apex. Hoffmann admits that small bronchiectatic areas are not infrequent in cases where there have been circumscribed processes in the apices and a tendency to recovery by subsequent fibrosis. In this latter category Solly places his case.

9. Obstetric Accidents.—De Lee holds that the pregnant woman is neglected in general practice. Patients are not examined to ascertain the size of the pelvis and to see if the heart, lungs, kidneys and liver are normal or if the pregnancy is normal, and he claims that by a moderate amount of intelligent supervision nearly all obstetric accidents might be prevented, or at least mitigated. Careful attention to the study of the patient and watching for symptoms of deficient excretion or toxemia would have much effect in obviating the occurrence of eclampsia. Family and personal histories should be carefully studied, both as to this and hemorrhages. As regards placenta previa, he says, if the woman has endometritis and if it has caused some puerperal anomaly before, look out for placenta previa. If there is even the slightest show of blood after the fifth month keep it in mind. He also advises careful examination to ascertain the presentation before labor, and to study the possibilities that may lead to puerperal infection. Lastly, he mentions the care of the child.

13. Sublamine.—Gottheil has used this remedy in an epidemic of ringworm that occurred in a large orphan asylum, largely due to overcrowding. Other remedies, creosote, formalin, croton oil, mercury bichlorid, iodin, etc., had been employed. About 100 cases were treated with sublamin and, aside from a certain number of chronic and probably incurable ones, they all did well. Its action was more rapid than bichlorid, as might be expected, as since it has equal bactericidal with greater penetrative power and can be employed in stronger solutions. There was no doubt that it was more effective than all the other remedies employed and less irritating. Bacteriologic examination revealed the fact that a parasite indistinguishable from that of ringworm could be obtained from apparently healthy scalps. It was possibly a less virulent type, or the usual form kept in depressed growth by prophylactic measures. They finally came to trust in macroscopic evidences for cure, leaving aside the bacteriologic tests.

14. Middle Ear Suppurations.—Dench's article goes at length into the treatment, etc., He recapitulates as follows:

In all cases of persistent and profuse aural discharge the radical operation is the operation of election. In cases of recurrent aural discharge, associated with lesions of the upper air tract, this tract should first be put in a normal condition.

In case of persistent but slight discharge from the ear, the operator may advise the removal of the carious ossicles, together with thorough curettement of the middle ear through the external auditory meatus. It should always be explained to the patient, however, that this operation is a tentative one, and that the more radical procedure may be necessary later.

16. Urethral Stricture.—Spooner, in his article on urethral stricture, gives its definition, anatomy, symptoms and course, with illustrations explaining the types.

17. Tuberculosis.—Pottenger insists on the importance of educating the public as to the methods of checking tuberculosis. He says its communicability must be impressed on the minds of the people, but these facts must not be exaggerated. There is no danger in associating with tuberculous patients if they are careful and follow the necessary precautions. As regards notification, he thinks it works in favor of the afflicted instead of against him. It would not be for public use, but simply for the information of the health officer.

21 *Some Observations on Blood Pressure in the Insane. William R. Dunton, Jr.
22 *The Formation of Loose Cartilages in the Knee Joint. E. A. Codman.

20. Parasyphilitic Affections.—This paper, the author states, is practically a condensation of Fournier's book with comments and quotations from other sources. He reviews the various post-syphilitic conditions.

21. Blood Pressure in the Insane.—Dunton has experimented with the use of the Riva-Rocci manometer on a considerable number of insane, and concludes:

1. The findings of other writers that (*a*) the blood pressure is increased in depressive states and decreased in excited states, and (*b*) that the motor condition has a greater influence on the blood pressure than does the mental condition, have been confirmed.
2. A moist skin has no especial influence on the blood pressure, although active perspiration may.
3. There was no constant daily variation, as has been noted by Schaeffer and others.

I feel that further conclusions are not justified by the cases presented here and others which are in a too incomplete state to justify publication. This paper will have fulfilled its mission if others are stimulated to observe blood pressure.

Too much importance should not be ascribed to this symptom. Its accurate observation has its value, and will probably have a greater value later when we have a better knowledge of how it is influenced by various bodily conditions. The general clinicians are adding to this, and we should do our part by observing how it is influenced in mental affections.

22. Loose Cartilages.—Codman has skiagraphically investigated the etiology and formation of loose cartilages ("joint mice") in the knee joint, which he says must comprise two injuries: one to depress the cartilage and one to free it. He has observed three stages and illustrates them by skiagrams, and has produced the first stage experimentally on the cadaver. The practical surgical point to be learned from the studies he has made is that in operating the articular surface of the internal condyle should be inspected. Torn or displaced semilunars do not show by the *x*-ray.

23. **Genito-urinary Diseases.**—The points made by Thompson in this article are especially the high tension pulse of nephritis, which he considers due to an agent similar to adrenalin in the blood, causing kidney shrinkage and diminished urea excretion. Aconite he finds the best vasodilator and restorer of the urea output. He remarks also that in urine examinations we are apt to give our attention too exclusively to discovering what ought not to be found in it. There are many cases that suffer from too little elimination of urea, due to gastro-intestinal disorders, and there is a close relationship between the alimentary canal and urea elimination by the kidneys. The tension of the pulse in these cases of functional renal inefficiency is low instead of high. The patients feel worse in the morning and better in the evening, as if there were some nocturnally generated poison in the blood. In these cases he would give a biweekly dose of mercury alternated with compound licorice powder and the steady administration of intestinal antiseptics, such as sodium or ammonium benzoate or capsules of salol with castor oil. He also alludes to certain emergencies that may occur, such as septic infection of the kidneys in the course of chronic nephritis, and in conclusion describes a perineal pad which he has found beneficial in cases of chronic spermatorrhea.

24. **Pyelitis.**—In the nine cases reported by Brown the demonstration of a considerable quantity of albumin in the urine was of the greatest possible value in making a diagnosis of pyelitis. In a number of these it was the first thing to call attention to infection of the kidneys. He thinks that in any case in which in association with pyuria there is a considerable albuminuria, there is a great probability, if not a certainty, that an infection of the kidney is present except in those cases where the albumin is due to a high grade of hematuria or to nephritis, in which case the presence of casts will demonstrate the cause of the albuminuria.

27. **Convergent Strabismus.**—Craig dwells on the importance of early and systematic efforts in the direction of improving the eye in cases of convergent strabismus and outlines the different procedures. In conclusion he calls attention to the following points which summarize his ideas on the subject:

1. The earlier the child is seen, the better the prospect for a cure.
2. The vision of squinting eyes can, in a majority of cases, be improved and some function restored if treatment is begun early.
3. A small percentage of cases of convergent squint can be cured by mydriatics, glasses and proper exercises alone, without operation.
4. The correction by non-operative methods is much to be preferred, as the motility of the eye is more perfect and the deformity produced by sinking of the caruncle is avoided.
5. Operative procedures should be employed in those cases in which non-operative treatment, after a thorough trial, has failed, and in those cases in adults in which we operate for the cosmetic effect.

34. **Kidney Decapsulation.**—Tyson and Frazier report a case and comment on the procedure. (See Society Proceedings, this issue.)

37. **Aspidospermin.**—This product of the well-known quebracho blanco drug has been experimented on by Wood and Hoyt, who find that it leads to increase in the amount of air moved in the lungs. This seems to be independent of any increased muscular activity or changes in the blood, and is probably due to stimulation of the respiratory center. Further researches, however, on the action of the drug are necessary to determine its precise value in practical medicine.

43 Ocular Incoördination and Cerebral Reflexes. F. Park Lewis.
44 Smallpox. William A. MacPherson.
45 Intestinal Obstructions. W. C. Phelps.
46 The Cure of Hernia. Gilbert D. Gregor.

40. **The Pulse in Typhoid.**—In two cases here reported with temperature records the course of the pulse was not in accordance with the temperature curve in typhoid fever. Bassett, therefore, concludes that the pulse does not follow the temperature or indicate the severity of the disease. Cases in which the pulse rate has not at any time in the course of the fever risen above 100 have proven fatal. The fact is, however, that slow pulse occurs with high temperature so seldom in typhoid fever that it is not mentioned by some authors.

42. **Spurious Gastric Diseases.**—The difficulty of always recognizing the nature of the apparently gastric symptoms is noticed by Jones, who remarks on the various causes of pain in the epigastrium, and the need in all cases of gastralgia of a differential diagnosis between the rather rare essential gastralgia and cholelithiasis. In the absence of symptoms and physical signs of gallstone colic the diagnosis is not always readily made. Vomiting is not a sure symptom of gastric disease. It may be due to cholecystitis, uremia or other causes. Appendicitis in its various phases and effects needs attention. In a good many cases local evidences are not so advanced that they are definite and easily determined. Reflex hyperchlorhydria may confuse the diagnosis. Pancreatic disease is another condition which, while relatively uncommon, may be confusing. Obscure tubercular peritonitis that causes no tumor may give rise to gastric symptoms. Heart lesions may also simulate gastralgia. He reports a case in which rupture of the heart was thus mistaken. Angina pectoris sometimes simulates gastralgia, and this should be borne in mind if gastralgia yields to nitroglycerin. Arteriosclerosis, arteriospasm and syphilis may also cause confusion, but the use of the iodids in the latter case will show the nature of the condition. There may also be true sclerosis of the arterioles of the stomach, causing ulceration, or diaphragmatic pleurisy may incite reflex pain in the gastric region, and only close study will determine the true nature. In his experience, he says, pain in the stomach is very rarely the result of pelvic disease, while vomiting is a common result. Disease of the pelvic organs is one of the causes of spurious gastric symptoms. We should be on the lookout for pelvic disease that may elude a superficial examination. Lastly, he mentions eyestrain as a cause of various stomach symptoms.

October.

47 Lupus Erythematosus. Alfred B. Grosse.
48 The San Francisco Quarantine Station. Hugh S. Cumming.
49 *A Few Illustrative Cases of Diphtheria. Fred G. Burrows.
50 *Abdominal Drainage. Stanley Stillman.

49. Diphtheria.—Burrows points out that the mortality and morbidity of diphtheria are greater in California than in other parts of the United States, nothwithstanding the fact that the climate of California ought to be less favorable to its extension than those of eastern parts of the country. He reports a number of cases and believes that if proper attention to the antitoxin treatment be given, the death rate and morbidity can be very decidedly lowered. He thinks that 99 per cent. of the cases can be saved in the California climate if properly taken care of and treated early with antitoxin.

50. Abdominal Drainage.—Stillman would limit drainage after intraperitoneal operation to cases where there is a single or multiple walled-off collection of pus or where necrotic tissue must be left behind or those where the intestine is seriously damaged and the suturing is faulty and likely to give way.

Albany Medical Annals.

October.

51 Acute Ulcerative Endocarditis. Samuel B. Ward.
52 *Varicella, with Report of an Unusual Epidemic. Spencer L. Dawes.
53 *The Surgical Treatment of Malignant and Non-Malignant Diseases of the Stomach. Albert Vander Veer.

52. Varicella.—Dawes reviews the symptomatology and etiology of varicella and discusses its relations with variola. He thinks the strongest argument for the duality of the diseases is the age question. Though cases of varicella do occur in adults, to all intents and purposes it is limited to the first fifteen years of life. During these years, if variola occurs it is severe while varicella is almost invariably mild. He remarks on the slight mention which this disorder receives in text-books, while other diseases which can not be more serious and are certainly less important in their etiologic relations are given much more consideration. Four cases are reported.

53. Diseases of the Stomach.—Vanderveer discusses the treatment of malignant and non-malignant diseases of the stomach, describing the operations, and concludes that gastroenterostomy can be applied to all forms and conditions of pyloric stenosis and is preferable to resection of the stomach in many cases, having less mortality and the possibility of good results being fully as great. Next to this he believes that gastrectomy is the best operation, but its utility is very limited. In its performance great attention should be paid to the removal of the lymph glands, as much of the permanent success of the operation depends on this point.

Fort Wayne Medical Journal-Magazine.

54 *Some Things to Be Remembered in Surgery. J. C. Fleming.

54. Things To Be Remembered in Surgery.—The special points emphasized by Fleming are the importance of hot moist dressing in cellulitis, the value of picric acid in burns of the second and third degrees, the bad policy of probing bullet wounds in general, the fact that gunshot wounds of the extremity and chest require simply watchful expectant treatment, while those of the abdomen require immediate laparotomy, and those of the brain require operative interference and removal of the bullet if possible.

September.

55 Diet and Drugs in Nephritis. William S. Gordon.
56 *Methods to Hasten Epidermization, with Special Reference to Skin Grafting. Stuart McGuire.
57 Chyluria. M. D. Hoge, Jr.

56. Skin Grafting.—The various methods of treatment of raw surfaces in order to hasten epidermization are noted by McGuire, who speaks in favor of the use of oleaginous dressings which have fallen into unmerited disfavor. Dry dressings he does not favor, as he thinks their good effects are only temporary. He finds considerable benefit from the treatment of granulating wounds by the use of dressings that supply food directly to the cells. Such he finds furnished in Valentine's meat juice, diluted in three parts water, and applied on cotton as a moist dressing. It does good for a short time, but then loses its effects. When the pale granulations become pink and healthy it should be discontinued. Alterative dressings have their place as well as the protective. Most of his article is devoted to a description of the methods of skin grafting, and he especially notices his experience with the use of heterographs. He has had occasion to test whether the skin of the negro would lose its pigment on a white person, and has found in a colored man that white skin grafts retained their color. He says for obvious reasons this has deterred him from reversing the experiment and grafting negro skin on a white man. He has had good results with the use of pigskin grafts, showing clearly that pigskin will grow under these circumstances. Dr. William Flegenheimer has reported a case of successful pigskin grafting by Wolfe's method, and Dr. Browning of the University of Virginia has personally reported to him another.

58 A Case of Filariasis Observed in Maryland. William F. Lockwood.
59 *The Care of the Insane. Frederick Peterson.
60 *A New Treatment for Wry-neck. Leonard K. Hirshberg.
61 Maryland's Need of a Mountain Sanatorium for Indigent Consumptives. Henry Barton Jacobs.

59. Care of the Insane.—Peterson describes the advance that has been made in the care of the insane in New York state, the thoroughness and perfections of the state care, improvement in administration, rise of scientific standards in the hospitals and the great increase in the comfort and care of the patients. These all have been brought about with a diminution of the expense of maintenance.

60. Wry-Neck.—In the treatment here described by Hirshberg he advises the use of the faradic current over the sterno-cleido-mastoid and trapezius of the healthy side. Three cases are reported.

62 Relations of the Medical Profession and Public to Each Other; Responsibilities of One and Demands of the Other; Work and Achievements of the Profession, and Benefits and Blessings Received by the Public. William S. Christian.
63 *Treatment of Eclampsia. J. M. H. Rowland.
64 *The Salts of Uranium in Diabetes, with Some Remarks in Regard to Their Physiologic Action. William R. Jones.
65 Urinary Analysis in Chronic Bright's Disease. M. D. Hoge, Jr.
66 The Terminal Symptoms of Chronic Bright's Disease. William S. Gordon.

63. Eclampsia.—The idea of Rowland's paper is to impress on the reader that more care of the pregnant woman is desirable and possible and that the toxemia of pregnancy may easily be prevented, and even the severer toxemias of pregnancy need not in the vast majority of cases cause eclampsia if properly managed. That immediate forcible dilatation of the cervix and delivery in eclampsia is not always justifiable, though the early delivery of the child is desirable when it can be accomplished without serious injury to the mother. The use of chloroform and morphin has probably been overdone, and the use of chloral and normal saline solution, hot packs, nitroglycerin and veratrum viride has been neglected or these measures have been improperly used. Other things being equal, the constant, intelligent attention of the physician during the whole period of the attack will be successful in causing recovery in a very large percentage of cases.

64. Diabetes.—Jones recommends the use of uranium nitrate in diabetes. It has, he says, a powerful effect on metabolism, and the patient's general condition improves while under its administration. The tormenting thirst, extreme weakness, excessive urination and glycosuria are gradually relieved. Dr. E. J. Moseley reports a case of diabetic ulceration which rapidly healed under the internal use of the salt after resisting all other methods. In every case in which Jones has employed the drug he has seen great improvement. He reports a case of advanced diabetes mellitus in which uranium nitrate was given in a dose of one-fourth a grain three times a day,

with occasional intermissions of three days, for about two months. The patient began to improve from the first, and at the end of that period the restrictions on the diet were gradually removed with no return of the glycosuria, and eighteen months later the patient was apparently in perfect health.

Archives of Pediatrics, New York.
September.

67 *Infections of the Newborn. Samuel McC. Hamill and William R. Nicholson.
68 *Injuries and Infections of Newborn Children. Irving N. Snow.
69 *Disturbances of Respiration in the Newborn. W. Reynolds Wilson.

67. **Infections of the New-Born.**—The infections described are mostly hemorrhagic and congestive conditions terminating fatally. A number of cases are reported with autopsies and bacteriologic studies. The staphylococci were present in nearly all; in one there was a bacillus resembling the colon bacillus. Streptococci and other organisms were also present in some of the cases. These infections occur most frequently in the maternity hospitals, and Hamill and Nicholson are inclined to consider them largely due to careless nurses. The greater frequency of air infection is not supported by facts, for in nearly all the cases there was a mixed infection. The symptoms may include profound toxic conditions, emaciation, nervous phenomena, skin eruptions, icterus, fever or diarrhea, etc. As regards diagnosis, the authors remark that any elevation of temperature, notwithstanding the frequency of fever in early infancy, should arouse suspicion. In most cases which they have seen, enteritis has been an early symptom, and next in order, perhaps, the papulovesicular eruption on the skin of the neck, face, shoulders or forearms, hence, if one sees this combination of fever, green mucous stools, skin eruption and rapid emaciation, one is justified in considering the condition an infectious one. Several cases which they studied postmortem had been diagnosed inspiration pneumonia. Differentiation between blood infection and lung involvement on the basis of the symptoms and physical signs is sometimes not possible. The prognosis is bad. For prophylaxis they advise greater care in the handling of the cases by the nurse, especially the proper toilet of the mouth. Every nurse who has handled the bedding of a patient, treated fissured breasts, emptied a bed-pan or changed a napkin, should be most careful in preparing her hands before she does anything to the mouth of these infants. The recognition of fissure or any other pathologic condition should cause an immediate withdrawal of the infant from nursing. The practice of continuing suckling under these conditions should be condemned. A change of environment is sometimes successful in streptococcus infections, and Delestre has claimed good results from the withdrawal of small quantities of blood, 2 or 3 c.c. or more, following it with the injection of a little larger quantity of artificial serum. The authors question the possibility of getting sufficient blood by a single bleeding to have much effect, judging from their difficulty in securing blood for cultures. Medicinal treatment is that of the symptoms, supplemented by vigorous stimulation and good nourishment.

68. **Injuries and Infections of New-Born Children.**—Snow analyzes the death records of Buffalo and compares them with the European statistics of Eröss. He finds that the mortality in Buffalo is greater in the first week. It would appear that more children die there from the accidents of parturition and fewer from infections than in Europe. The occurrence of cerebral and meningeal hemorrhages, etc., is noted. The former may occur in small children that are easily born. The prognosis, of course, of intracranial hemorrhage is bad. Snow reviews a series of cases of diarrheal diseases in new-born children among well-to-do families with good hygienic surroundings, and while the mode of infection is obscure, he is convinced that the mother's milk was the cause in some cases. In one instance the child was probably infected in the parturient canal, possibly by swallowing infected amniotic fluid.

69. **Respiratory Disturbances in the New-Born.**—The first of these conditions which confronts the practitioner is asphyxia; the next congenital atelectasis. Cases have been reported where there has been respiratory failure apparently of bulbar origin. In opposition to these cases are those due to toxic influences or alimentary disturbances of which Wilson gives instances. Dyspnea may arise from congenital conditions, such as cardiac malformations. The dyspnea of pneumonia lacks the paroxysmal attacks, the breathing is frequently irregular and of the Cheyne-Stokes type. The fever and physical signs may be absent in weakly children so that a differential diagnosis between pneumonia and atelectasis is impossible. Congenital stenosis with dyspnea may occur, and dyspnea of the convulsive type arise from enlargement of the thymus gland. When signs of intrathoracic trouble are wanting, the symptoms may point to alimentary disturbance. In these cases dyspnea is not usually the primary manifestation; green stools, fever, anorexia, etc., are likely to precede the attack. Diaphragmatic hernia offers a complexity of symptoms in which dyspnea predominates, though it is rare and probably very seldom causes confusion in the diagnosis. Rapidity in respiration is commonly met with, either paroxysmal and transient or continuous. Dyspepsia and febrile conditions may be the underlying causes. It may be a symptom of the common pulmonary affections. The author reports a case in which respiratory disturbance was associated with gonorrheal ophthalmia, and the septic intoxication of the child was probably the result of a mixed infection. This blennorrhea in itself would hardly account for the condition. The source of infection was obstetric rather than congenital.

77 *The Diagnosis and Treatment of Obscure Syphilitic Lesions of the Eye. E. F. Snydacker.
78 Psychotherapeutics. E. A. Edlen.

70. **Spinal Injury.**—Mammen reports several cases of treatment of severe spinal injury, and formulates the following general principles as applicable to this class of injuries: 1. Where no fracture or dislocation has occurred, but a degree of paralysis exists, absolute and physiologic rest is of importance. 2. If fracture and dislocation occur, as in fractures elsewhere, there should be an attempt to restore the parts to their normal condition by manipulation, extension, and if need be, operation. 3. After injury or operation the spinal column should be held in position by a proper immobilizing apparatus, jacket, splint, and jury-mast, or combinations of these. Where pressure exists from depression of the arch or from hemorrhage, laminectomy should be resorted to as early as possible.

75.—This article has appeared elsewhere. See THE JOURNAL of July 18, ¶22, p. 205.

77. **Syphilitic Lesions.**—Snydacker divides syphilitic lesions into two classes: 1. Those due primarily to syphilitic poisoning amenable to specific treatment; 2, those secondary post-syphilitic changes which are not thus amenable. Primary ophthalmic atrophy must be reckoned with the latter as also choroidal changes, retinal lesions, etc., that fail to yield to mercury or iodin. Clinically all specific lesions of the eye are obscure. A history, examination, exclusion and therapeutic tests are requisite. In the treatment of eye lesions of the first class we employ antispecific remedies; in the latter we avoid such remedies, employing rather a tonic and strengthening form of treatment. He reports cases.

86 Two Peculiar Cases of Fragilitas Crinium. George T. Jackson.
87 Note on a Rapid Method of Diagnosis in Leprosy. Francis J. Shepherd.

79. **Precancerous Affections of the Skin.**—Among these Hartzell notices inflammations peculiar to workers in tar and paraffin, chimney sweeps' dermatites, which are known to undergo malignant change, and also lupus vulgaris, which in a small proportion of cases is followed by epithelioma. Other forms of cutaneous tuberculosis, such as the varicose type, may also thus terminate and erythematous lupus has been observed to thus change. Ulcerating lesions of tertiary syphilis in rare instances become the seat of cancer. New growths of the skin, warts and pigmented nevi show the greatest tendency to such change. Cicatrices arising from any cause; chronic leg ulcer, especially cicatrices from burns, various forms of circumscribed keratosis, such as cutaneous horns, callosities, the palmar and plantar lesions resulting from arsenical poisoning, and senile keratomata form an important group of precancerous affections. He calls attention to the fact that in a considerable proportion of cases marked hyperidrosis precedes the appearance of the keratosis. The most frequent and perhaps the most important form of precancerous keratosis, the one most deserving of the term, is the so-called senile seborrhea of the French authors, or the senile keratoma of Besnier, which is the better title. It occurs as pinhead to dime-sized, more or less elevated, friable and slightly greasy, or dry and hard, yellow brown or black crusts which are firmly adherent to the skin. When forcibly removed the underside of these crusts shows numerous small spines, which have filled the dilated mouths of the follicles, and the skin beneath is moist and red or frequently superficially ulcerated. There are usually no subjective sensations. It occurs most frequently in the forehead, upper parts of the cheeks, the nose, back of the hands and in those engaged in manual labor or exposed to the weather. In its course, the disease is variable. Many of the patches remain unchanged for years; a few are gradually transformed into superficial epitheliomatous ulcers which slowly enlarge, with all the characteristics of a papillomatous epithelioma. Notwithstanding its frequency and tendency to terminate in malignant disease, it is little noticed in works on dermatology. Almost the only adequate account is that given by Dubreuilh, presented at the International Congress of Dermatology in 1896. Within the past year or two Hartzell has studied a number of these cases and gives the pathologic findings with illustrations.

82. **Dermatitis Venenata.**—White offers in this article a supplementary list to that given in his work on dermatitis venenata in 1887. He mentions first the irritants generally recognized, among them certain new hair dyes such as chlorhydrate of paraphenylene-diamin and "aureole," containing metol, amidophenol-chlorhydrate and monoamidophenylamin. Several instances of dermatitis from these have been observed. He also refers to cases reported from phenyl-hydrazin-hydrochlorid, salol, orthoform, resorcin, pyoctanin, creolin, iodvasogen, kerosene and electricity. He remarks that while petroleum is not irritating, kerosene applied for parasites is capable of producing a fine papular dermatitis. He has also seen eruptions follow application of electricity. Dermatitis produced by the *x*-rays does not require mentioning. In his second class are irritants not generally recognized. He mentions "aurantia" (hexa-nitro-phenyl-amin) a dye used to stain leather yellow; green ebony, guiacum, hops, which belong to a dangerous family (the *Urticaceæ*), *Heracleum giganteum, Angelica archangelica,* hyacinth bulbs, *Cotoneaster microphylia,* an ornamental plant belong to the *Rosaceæ* family, *Humea elegans,* the ginkgo tree, etc. Of the suspected plants he mentions the trumpet vine and the woodbine, which are sometimes credited with being poisonous, but are probably confused with the *Rhus toxicodendron.* He also quotes from Dr. Chestnut of the Poisonous Plant Investigation Bureau, who mentions the common radish, the common dogwood, the commercial pawpaw, common dog fennel and the common field daisy as occasionally irritating to the skin; also several species of hypericum and buckwheat, and the laporteas, which are, however, confined to the tropics and only seen in hot-house cultivation.

85. **A New Drug Eruption.**—Politzer reports cases of dermatitis from the use of mesotan which has been considerably used as an anti-rheumatic by local application. He also mentions that some eruptions have followed the use of aspirin, but they were evidently due to idiosyncrasy and not, as in his case of mesotan dermatitis, the effect of the prolonged action of the drug.

92 The Sphygmomanometer. Richard L. Sutton.
93 Anatomy and Physiology of the Urethral Muscles, with Especial Reference to the Diagnosis and Treatment of Gonorrhea. F. Baumann.

88. **Scarlatina.**—The serum therapy of scarlet fever is favored by Schiller, who thinks all streptococci are closely related, and that any antistreptococcic serum ought to have some effect on scarlet fever cases. In his own experience here reported he was unable to get the Moser and Tavel serum, but obtained material made probably somewhat after the Marmorek method which he employed in two cases, both septic. A decided change was noted after the serum injection. The earlier treatment, consisting of the use of Credé's ointment, the care of the mouth, strychnin, dietetic and hydropathic measures, caused no improvement, but a change for the better was seen after the serum injections. In both the cases there was a relapse which he credits to renewed invasion of the system by the streptococci. Reaction from the serum was again prompt.

89. **Typhoid Cholecystitis.**—A case is reported by Burlew and he discusses the literature, tabulating cases which are notable as bearing on the relation of the typhoid bacillus to gallstone formation and as showing the length of time in which the bacillus may persist in the gall bladder after the primary attack of typhoid, producing at remote periods cholecystitis and cholelithiasis. The occurrence also of suppurative cholecystitis of typhoid origin, complicating direct attacks of typhoid fever, is possible. A typhoid cholecystitis may develop without the co-existence of a previous attack of typhoid.

90. **Appendicitis.**—Moyer raises the question as to the medicolegal bearings of traumatism and appendicitis, and quotes authorities. In the case he observed, appendicitis occurred the seventh day after a fall, to which it was attributed. He questions to some extent the probability of the appendiceal lesion being the result of so remote an injury.

91. **Pneumonia.**—From 782 consecutive autopsies in the Cook County Hospital and a discussion of the literature, Kerr summarizes as follows:

1. The maximum frequency of deaths from pneumonia is from 35 to 40 years, while of those due to all causes it is in the next decade. 2. Fatal cases are somewhat more frequent in males. 3. There is a preponderance of unilateral cases, of the right side over the left, and of the lower lobe over the upper lobe. Crossed pneumonia is rare. 4. A majority of the cases are in the stage of gray hepatization. 5. Edema of the lungs and bronchitis are common, while abscess and gangrene of the lungs are rare. 6. Acute parenchymatous changes occur in the parenchymatous organs with a marked frequency. 7. The serous membranes are involved in the following proportions:

Pleuritis	70 per cent.
Pericarditis	12 per cent.
Endocarditis	8 per cent.
Meningitis	6 per cent.
Peritonitis	5 per cent.
Arthritis	very rare.

8. Pericarditis occurred with pneumonia of the lower lobes in all but 2 cases, and of the right middle lobe in these 2 cases. In Steven's series it is found with the upper lobe alone in 4 cases. 9. The preponderance of vegetative endocarditis and the preference for the mitral valves differ from the usual experience. 10. The frequency of meningitis associated with endocarditis is noteworthy. 11. Jaundice does not seem to be accompanied by any uniform change in the liver. 12. The frequency of occurrence of pneumonia as a terminal infection is noteworthy. The presence of chronic pathologic lesions in a large number of cases is also remarkable. These findings are of importance from a standpoint of prognosis chiefly.

2. **Intra-abdominal Anastomosis.**—Makins' paper was abstracted in THE JOURNAL, Aug. 29, 1903, p. 571.

Dr. E. S. Bishop followed Makins. He says in summarizing his points:

The use of decalcified bone bobbins is advisable in operations for union in the gastric region and the upper part of the small intestine, mainly because they act as a protection during the early stages of union and because the intestinal contents in these segments are liquid and possess certain chemical and digestive properties, from which the line of union in these regions needs to be protected. The use of such appliances is doubtful in the lower small intestine and is absolutely contraindicated in the large, mainly because of the solid or semi-solid nature of their contents. . . . In choosing a mode of suture, that one is to be preferred which gives the most perfect security against leakage in consequence of its yielding to the peristaltic strain, exposes itself the least and so minimizes the irritation and consequent adhesion of surrounding peritoneal surfaces, by which later obstruction may be produced, and which removes the inevitable diaphragm formed by the necessary inturning of the bowel ends, so as to leave a smooth internal surface. The use of forceps, . . . or the preliminary crushing of the intestine . . . all of which are based on the idea of producing sphacelation of the inturned edges of the gut, are of very doubtful value, are associated with unnecessary risk of later perforation, and should not be preferred to simple suturing or to suture over some absorbable and protective appliance.

He advises a previous colotomy in removal of neoplasms, etc.

In further discussion Elsworth says he finds the Murphy button a satisfactory method; others say they have supplanted it almost entirely with suture. Mayo Robson thinks the Murphy button a dangerous appliance.

3.—This paper was abstracted in THE JOURNAL, Sept. 12, 1903, p. 678.

4. **Posterior Gastrojejunostomy.**—Hall mentions his method, which he calls the supracolic operation, the posterior wall of the stomach being reached by an opening made in the gastrocolic omentum instead of the transverse mesocolon. The gastrocolic omentum is a thin, practically bloodless membrane, and there is, therefore, no chance of interference with the vascular supply; there is no risk of contraction of the opening causing pressure on the loop of the jejunum and hence no necessity for suturing the margins of the aperture to the stomach wall as recommended in the case of mesocolon:

An incision of 3 in. at once exposes the gastrocolic omentum. The loop of the jejunum is hooked up with the index finger and clamped. A fold of the posterior wall of the stomach is drawn through the aperture in the gastro-colic omentum, and, after shutting off the peritoneal cavity with gauze, the anastomosis is completed outside the abdomen. In making the anastomosis I use a double row of continuous suture, an inner one of catgut to unite the cut edges and including all the layers, so as to control any bleeding points, and an outer serous suture of silk. I have given up all mechanical appliances, because I find I can do better without them. In this, as in the old anterior operation, the loop of the jejunum lies in front of the colon. I do not believe that this is any disadvantage; indeed, I am strongly of the opinion that the objection raised against this arrangement is entirely a false one. I have had the opportunity of examining two subjects postmortem on whom gastrojejunostomy had been performed for malignant disease.

He tabulates a number of cases and reports a trial of this method, which he thinks combines the use of both anterior and posterior operations and avoids their disadvantages.

5. **Gastro-enterostomy.**—Eccles calls attention to the danger of gastro-enterostomy from extensive manipulation necessitated

by delivery of the stomach for the proposed operation. In many cases either of sarcoma or ulcer which is apparently healed but placed under tension it may lead to perforation and peritonitis or hemorrhage. He reports a case of this kind.

8. **Separation of the Acetabular Epiphysis of the Femur.**—Several cases are reported by Robinson which he thinks establish the following points:

1. That we have to deal with genuine cases of separation of the acetabular epiphysis. 2. That injury, although it determines the separation, is aided in its effect by an antecedent change at the epiphyseal line. 3. That this pathologic change is presumably similar to what occurs in the coxa vara cases of adolescence, as suggested by Springel.

16 *Some Investigations on the Urine of Children. Arthur W. Fuller.
17 *Some Observations and Comparisons on the Dietetic and Drug Treatment in Chronic Pulmonary Tuberculosis. D. Lloyd Smith.

11. **Syringal Hemorrhage of the Spinal Cord.**—Gowers calls attention to the possible presence of cavities in the spinal cord due probably to defective development and the dangers which they incur by hemorrhage into their lumen. He refers to cases in which dissection showed that this has occurred and reports other cases where symptoms pointed, he thinks, to this condition. There was local paralysis and anesthesia without any evidence of disease of the brain and pointing directly to a special local hemorrhage. It is seldom fatal and the diagnostic question is of considerable importance. When the death occurs it seems to be the result of erosion of extravasations into the substance of the cord or to a secondary spreading of the inflammation. He notices the importance of rest in these cases, not always prone on the back which might favor hemorrhage but in any position that would less favor the additional escape of blood. The importance of posture is especially insisted on.

14. **Antityphoid Inoculation.**—Wright gives tables showing the incidence of typhoid and its death rate in India during 1901 and in Lord Methuen's column at Modder River, South Africa, from December, 1899, to March, 1900. In both a certain portion of the troops were inoculated with the antityphoid serum. The incidence rate of typhoid was diminished to less than one-half, and the mortality rate as given in the Indian army was only one-sixth as great among the inoculated as among the uninoculated.

16. **The Urine of Children.**—Fuller has studied the urine of 63 healthy children and finds his results agree very fully with those of Churchill of Chicago, reported in the Archives of Pediatrics for 1898, p. 646. It appears that American (Chicago) and London children excrete a smaller amount of urine than those of Germany, Austria and some other countries.

17. **Tuberculosis.**—Smith publishes the diet chart of the Manchester Sanatorium and gives particulars of a series of cases treated with various drugs. He calls attention to the fact that the diet is of paramount importance. A meat diet supplies a physiologic want, but it should be employed to suit the patient's case, and especially in those with gastric disorders. With an abundant mixed diet cod-liver oil is not necessary. The object is not to make the patient a flabby mass of fat, but to turn out a solid, robust individual. A gain in weight is not everything. It sometimes occurs without improvement of the pulmonary condition. Here comes in the importance of supervision of the diet and vigilance of the medical attendant.

22 The Causation of Cancer. Alex. Theodore Brand.
23 *An Inquiry Into the Relations of Leukemia and Tuberculosis. W. J. Susmann.

19. **Addison's Disease.**—Adams concludes that in a certain number of cases of Addison's disease benefit is derived from the exhibition of some form of suprarenal, but it is impossible to determine just what cases these will be beforehand. Disappointment is likely to follow, though less so, he thinks, than in most alternative methods of treatment. The problem seems to be to get a sufficient and continuous dose of the pure active principle unchanged into the blood stream. Intravenous injection is impracticable.

21. **Diabetes.**—Lorand has experimented with test meals to determine the tendency to alimentary glycosuria in children of diabetics and finds that it is somewhat marked. These cases are often precocious, mature early and have early senile changes. Attention must be paid to the hygiene, the patients should lead a frugal life, avoiding rich foods, especially if meat is taken simultaneously with large quantities of sweet and amylaceous food. They should not follow occupations incurring great mental strain and he would advise against athletics. Slight accidents may produce traumatic diabetes.

23. **Leukemia and Tuberculosis.**—Susmann finds leukemia of either type rarely complicates tuberculosis, but the lymph type occurs two and a half times more frequently than the splenomedullary and as a complication it is six times more frequent in the male than the female. Tuberculosis may be latent and obsolete or occur as a terminal infection, or may be latent and lighted up by the leukemia. The last is the most frequent. When the two diseases are combined there is a tendency for the total number of leucocytes to be diminished and the spleen and glands to decrease in size. This is possibly due to the excess of nucleo-albumin and the increased phagocytic power of the blood, both of which occur in the leukemic patient.

25 *Malarial Fevers in West Africa. R. Crofts.
26 Municipal Sewerage. (Continued.) F. Smith.

25. **Malaria in West Africa.**—The peculiarities of West African malaria are described by Crofts, who remarks that remittent fever is the most frequent type. Europeans of mature age are best suited to stand the West African climate; under 26 or over 50 are unsuitable ages to attempt it. The average European on the West African coast thinks little of his diet; he eats too many meat meals daily. The Irish and Scotch are not so likely to do this. Crofts thinks a little alcohol in the evening is better than total abstention. The average attack appears with pains across the loins, frontal headache and vomiting and soreness in the lower extremities. The backache is as constant as in smallpox. Drugs such as bismuth and opium given for the vomiting only aggravate the condition. The two most valuable diaphoretics he has found are antipyrin and antifebrin, especially the latter. He has not seen any ill effects from it; the dose should be 5 grains. A purgative such as calomel should be given, 5 to 10 gr.; no other can compare with it. On the first examination the patient's urine should be examined for albumin and bile and the lungs to be sure there is no pneumonia. He protests against the use of opium. Arsenic is of incalculable value; it is much better than quinin in these cases. The dose should be at first a large one and gradually diminished; the best form is the liquor arsenicalis. As for quinin, all the good that is in it can be obtained from about 15 gr. daily; there is no good in large doses. A high temperature above 105 is serious, and he advises sponging with cold water for these cases, followed, may be, by a wet pack. Albuminuria is common. The most frequent cause of death is cardiac clot, though this is not generally recognized. The heart's action should be supported, Carbonate of ammonium is given to diminish the fibrin in the blood. The patients must be fed, and if we can not feed by the mouth we must feed by the rectum. Most patients require alcohol early.

36. Sahli's Functional Stomach Test.—Habel and Humbert have given Sahli's "flour-soup" test a thorough trial in their clinical practice at Geneva (the technic was given in THE JOURNAL, xxxviii, p. 1477, '88). They describe the particulars of 23 cases, and state that their experience has fully confirmed the great value of the test. It is much simpler and easier than any others they know of; it shows the amount of food that passes out of the stomach in a given period, and the amount of gastric juice remaining in the stomach when the stomach tube is applied. It allows the proportion of acid in the gastric juice to be determined by itself, not diluted with fluids from a test meal. A further advantage is that one application of the stomach tube is all that is necessary. The dosage of the fat is sufficiently accurate for all practical purposes.

37. The Kidneys in Eclampsia.—Bar gives illustrations of the aspect and microscopic findings in a number of kidneys examined from women who had succumbed to eclampsia. Pronounced lesions were found in every one, and, in fact, he can not remember a single instance in his experience in which the kidneys of eclamptic subjects did not show gross pathologic lesions. In 4 of his present series of 24 cases the kidneys were profoundly affected; in 9 the lesions were of moderate and in 8 of slight intensity. In the remaining 3 the organs were not markedly pathologic. The lesions were all of the nature of those observed in toxic nephritis in which the action of some powerful poison rapidly destroys the epithelium of the convoluted tubules, diffusely affecting the rest of the organ, but less severely. Even in the mildest cases the lesions included ectasia of the convoluted tubules, and the capsule contained an albuminous fluid, but the intercanalicular tissue was approximately normal. The liver was affected in most of the cases, but not proportionately to the intensity of the kidney lesions, some of the mildest cases of the latter being accompanied by the severest liver lesions. The general impression derived from his research is that the findings indicate the action of some powerful poison suddenly attacking the kidney or liver, the diffuse lesions induced causing such perturbation in the functions of the organs as to be the cause of grave symptoms. It is possible that the liver is most affected in some cases, the kidneys in others.

40. Kidney and Liver in Fetus of Eclamptic Mothers.—In 80 cases of eclampsia in Bar's experience 37 of the children were stillborn. In 16 the fetus was macerated. In 21 cases the fetus succumbed after the first attack of eclampsia. Out of the 43 infants born alive, 27 died within three days. The fetal mortality was thus 80 per cent. in the 80 cases of eclampsia, and the survivors were all weakly children. The liver and kidneys of 17 of the fetuses were examined and marked congestion noted in all, with degenerative processes of rapid evolution similar to those observed in eclamptic women, but much less intense and less constant. They are apparently secondary, and derived by toxic action from the maternal organism. This view is sustained by their localization, frequency and analogy with those exhibited by the mother, although in neither case are the lesions pathognomonic. Even if the child survives, these vital organs are affected to such an extent as to hinder his normal development for a time at least.

47. Keloid.—Tschlenow reports a case and discusses the litature. He remarks that under the name keloid we understand a special disorder of the skin, which from many points of view recalls a new growth and should be counted as such, of a fibroma type. Keloid may be either primary, corresponding to the designation of the earlier authors as "true" keloid, or secondary or scar keloid. Hypertrophied scar, however, should be distinctly separated from this group. Clinical and histologic studies show that a marked distinction between primary and secondary keloid is not based on facts. Both have the same type of development: histologic alterations or marked increase of the connective tissue with decrease of the elastic tissues along the blood vessels. The cutis is to be regarded as a particular starting point of this growth. Its etiology is obscure. The chief factors seem to be a special, personal, family or racial predisposition, under the influences of which the skin reacts in keloid formations from slight irritation, not, however, to every irritation or in every part. This explains also the remarkable tendency to relapses. As regards the pathology, the vascular system undoubtedly plays a large part, but further investigations are needed. Keloid is neither a scar nor simple hyperplasia of the connective tissue. It is different in its structure from infectious granuloma and fibroma, but its proper classification is still impossible. The cause for its spontaneous cessation of growth is unknown. Its prognosis is generally not very satisfactory and the treatment is usually a thankless task.

54. Syphilis.—Schüller defends his former announcement of the discovery of a protozoön-like parasite in syphilis, made by him in the *Centralblatt für Bakteriologie*, xxxii, Nos. 5 to 9, 1902. He has investigated new cases and illustrates the results of his histologic and cultural studies.

58. Trichohyaline.—This is the name given by Vörner to a new substance found by him in the hair roots which differs from the former elements there discovered, the eleidin and keratohyaline, in chemical, physical and staining qualities. It differs from hyaline by its greater resistance to acids and al-

kalies, as also in its different staining reaction. It colors yellow with the Van Gieson stain, while hyaline becomes red. It is undoubtedly a product of protoplasm and occurs earlier than eleidin and keratohyaline. It can be observed in the earliest hair structure.

63 Der XXXI deutsche Aerztetag. S. Alexander.

59. Mistakes in Diagnosis of Pulmonary Phthisis.—Schmidt sounds the alarm that we are getting into the habit of diagnosing tuberculosis when there is really no necessity for so doing. Naegeli has shown that the liabilities are that we are all tuberculous—the practitioner has only to decide whether the tuberculous infection is latent or progressing. Infinitely more harm is done, Schmidt thinks, by needlessly frightening persons with the announcement that they have tuberculosis than would result from the overlooking of a few cases that later proved to be actually progressing tuberculosis. The serum and tuberculin tests are more valuable when they are negative, he asserts, than when they are positive. He has frequently encountered persons who have been rendered morally and physically unfit for any occupation by the needless diagnosis of tuberculosis. They go from one sanatorium and resort to another, sacrifice time and money and never are well because their alarm keeps them ill. Physicians are overzealous in diagnosing tuberculosis, and a halt should be called. The progress of the affection in dubious cases will soon solve the question, and still be in time for appropriate treatment. He calls attention to three sources of error in the diagnosis of clinical tuberculosis: First, the physical signs of dulness and retraction of the apex which are caused by an irregularly-shaped shoulder girdle. The second source of error is in hemorrhages from small foci of bronchiectasia, and the third is the pseudo râles and friction sounds made by the edges of the lungs. He describes 5 cases in detail in which tuberculosis had been diagnosed by several physicians on the ground of dulness and apparent retraction of the apex, but careful, repeated examinations during a long period and the negative tuberculin test demonstrated that this diagnosis had been erroneous. In one case the dulness and apparent retraction of the apex were caused by the effects of atrophy of some of the muscles of the pectoral arch; in 2 others by a slight scoliosis of the upper part of the thorax, and in the others by an extra high scapula. The number would be materially larger if he included those cases in which tuberculosis had been presumptively diagnosed. These anomalies of the shoulder girdle are by no means uncommon. The elevation of the scapula may be congenital or the result of rachitis, inflammatory retraction of the levator scapulæ, ankylosis of the shoulder, or it may be due to some defect in the trapezius. Small bronchiectasic foci may induce repeated hemoptysis and thus simulate a tuberculous affection. In a case he relates a physician of 35 had suffered from severe hemoptysis recurring once or twice a year since his student days. Although he presented no other evidences of tuberculosis he was regarded as a consumptive by competent authorities and treated accordingly. The circumstance that he had pronounced drumstick finger suggested the possibility of bronchiectasia to Schmidt, and careful examination of the minute quantity of sputum which the patient was in the habit of coughing up once every morning, revealed the presence of minute "Dittrich's plugs." Isolated râles could also be heard in the interscapular space. The case was evidently one of circumscribed bronchiectasia, with possibly also an anthracotic gland with a perforation in the vicinity of one of the main bronchi. Pseudo râles and friction sounds are heard at the margins of the lungs, principally at the lower margin in subjects with scoliosis. When encountered they will be found constant, but they have no pathologic significance so far as the lungs are concerned. Repeated examination and the constancy of the sounds always at the same spot and uninfluenced by position, coughing, etc., differentiate them. A young merchant of his acquaintance had been proclaimed to be tuberculous on the basis of these sounds, and for years had spent his days in the vain search for relief from them, living all the time in the shadow of tuberculosis, but not presenting any other signs of the disease. Schmidt examined him year after year, and always noted the same delicate crepitations, as from atelectasia, along the margins of the lungs, but nothing else that could be construed as pathologic. Schmidt assured him that the sounds were accidental, but was unable to convince him that the diagnosis of tuberculosis had been erroneous, and he has not dared to give up his invalid mode of life. Schmidt does not attempt to explain these pseudo râles, although he suggests marginal emphysema as a possible cause. The frequency of the latter, however, is out of proportion to the number of cases in which these sounds are heard. Alterations in the position and mobility of the pleural sinus by changes in the bony skeleton may likewise be suggested as a possible explanation.

60. Treatment of Gonorrheal Epididymitis.—Baermann of Neisser's clinic at Breslau proclaims that every epididymitis which appears during a gonorrheal urethritis, is due to local invasion of gonococci. The latter can always be found in the puncture fluid. In the overwhelming majority of cases of epididymitis an abscess rapidly develops, either from congestion with secondary destruction of the walls of the epididymis or from actual suppuration. In the latter case there is always more or less well-developed hydrocele, which is likewise due to the local invasion of the layers of the tunica vaginalis by the gonococci. In certain circumstances it is possible to find gonococci persisting for years in the relics left of an old epididymitis. Early puncture in epididymitis accompanied by signs of violent inflammation is advisable as a therapeutic measure. This evacuates the abscess before the walls of the epididymis have been injured by it. Puncture is likewise advisable in case of inflammatory hydrocele, as by its evacuation better conditions for circulation and absorption are provided.

68. Anti-Fat Treatment of Children.—Hellesen gives the results of study of the metabolism of a child affected with *adipositas nimia*, and discusses the subject of anti-fat treatment of children, commenting on the difficulties encountered. Limiting the intake of fats to one-fifth of the "balance ration" seems to be the best method for reducing corpulence. An albumin-fat dietary is more harmful than albumin and carbohydrate diet when the quantities are restricted. His experience indicates that under no circumstances must the anti-fat dietary be kept up for more than a few days at a time or the development of the child will suffer.

76 Beitrag zur Quadriceps-Plastik. S. Stiassny.

77 *Combating Venereal Disease. C. Fraenkel.—Die Bekämpfung der Geschlechtskrankheiten. (Commenced in No. 38.)

73. **Mueller's Operation for Spina Ventosa.**—Mueller operated on a dozen patients by excision of the morbid tissue of the spina ventosa and transplanting into the cavity thus formed a flap of periosteum taken from the neighboring long bone. The functional result years afterward has been excellent. Ehrhardt reports seven such transplantations undertaken on 6 patients. He found the procedure extremely simple, not requiring hospital care, and healing in at least three weeks. A complicating fistula proved no contraindication to operation. The patients were from 18 months to 15 years of age. Nine months have elapsed since the first case was operated on, and all of the children have movable fingers of normal shape and size. The method is not applicable when the joint is involved, but in all other circumstances seems to be by far the best method known to date.

74. **Significance of Oculomotor Paralysis for Topical Diagnosis.**—Bielschowsky reviews the publications on this subject which have proceeded almost exclusively from internists and neurologists, and gives cuts and a detailed description of a typical case. He mentions that no one to date has realized the importance of the information to be derived from passive movements of the head, turning it to one side with the eyes fixed on some special object. It is important in this and other tests of the movements of the eyes to note the behavior of the second eye. From the symptoms he describes he draws the deduction that the focus causing the disturbance must be to the front of the nucleus of the abducens, and have injured both dorsal longitudinal bundles, but probably only in certain sections. The fibers passing upward in each longitudinal bundle, which are the media of reflex stimulation of the muscles that turn the eye to the side during passive movements of the head, must have been still functionally active. The tract transmitting the impulse from the cortex to the nucleus region must also have been partially intact.

75. **Evacuation of Gallstones by Flushing the Biliary Passages.**—Kuhn flushes the biliary passages through a tube inserted in the fistula or during an operation, using physiologic salt solution under a pressure of 200 to 1,000 mm. water. It is possible to rinse the biliary passages in this way, obstruction to the flow indicating some obstacle in the way. Medicinal treatment can be applied directly to the lesion and the permeability of the passages can be ensured. He has never noted any inconveniences from this procedure, even when considerable force was applied, which caused a condition resembling that of a mild gallstone colic, fever, pains and slight icterus afterward. He commences with a pressure of 200 mm. of the water column and gradually increases to 500 mm. He has established certain formulæ for the behavior of the current, showing that it is possible by the flow of the water to determine whether there is an obstacle to the flow, whether the passages are normally permeable or whether they have been dilated by the frequent passage of stones. The washing away of gallstones by the mechanical force of the current is a valuable adjuvant to operation when there are innumerable small ones, but, of course, is not feasible with large impacted stones. In case of numerous small calculi he thinks it is impossible to remove them all during one operation unless the biliary passages are flushed again and again. In one case after every stone had been supposedly removed during the intervention which included ablation of the gall bladder, 40 small stones were brought away by rinsing out the upper biliary passages. Gallstone colic is merely the expression of increased pressure in the biliary passages caused by some obstruction to the escape of the biliary secretions. By inserting a tube and flushing these passages we create artificially the same conditions as in gallstone colic, distending the passages and forcing the contents along, but with the advantage that the physician is master of the situation and can control the condition, increasing the pressure at will and arresting the "attack" at any moment.

77. **To Combat Venereal Disease.**—Fraenkel argues at length to prove the superior advantages over the present systems of "controlled streets" for prostitution, that is, certain limited quarters set apart for prostitutes to live in, abolishing the brothels. These preventive regulations to be supplemented by personal prophylaxis. He remarks that the conditions at present in Berlin are more unbearable than in any other large European city, and that a respectable woman, even accompanied by gentlemen, can scarcely venture on the streets after dark without danger of seeing or hearing the most offensive things. All this is done away with in the cities that have introduced a system of "controlled streets."

79. **Tetany and Autointoxication.**—Loebl states that one or more of the cardinal symptoms of tetany accompany typical cases of autointoxication. In two-thirds of the cases of autointoxication in his experience he noted spasmodic contraction of some of the muscles, while examination of the urine in case of manifest tetany invariably disclosed evidences of disturbed metabolism, transient acetonuria, albuminuria and casts in the urine. Permanent injury of the kidney was not encountered in any case. He defines tetany, therefore, as an affection due to autointoxication affecting particularly the peripheral neuromuscular apparatus.

81. **Disturbances in Pubic Region in Case of Flat-Foot.**—Ehrmann gives several cuts to illustrate his contention that the altered static conditions in flat-foot cause disturbances in the pelvis with resulting injury of the pudendus communis, liable to be manifested by herpes and pains in the pubic region.

82. **Etiology of Baldness.**—Schein suggests as a possible explanation for baldness the excessive stretching of the skin of the scalp as the galea and epicranius develop as habitual in men advancing in years. This stretching of the skin entails nutritional disturbances rendering the hairs less resistant. Pohl suggested years ago that this stretching might be counteracted by local application of diluted acids and alkalies. He did not appreciate, however, the importance of the development of the epicranius and galea as the cause of the stretching.

83. **Surgery and Diabetes.**—Fellner operated on a woman of 40 on account of bilateral pyosalpinx. Symptoms of progressive diabetes had been noticed for fifteen years, with four abortions during this time after two normal deliveries. He is inclined to believe that the diabetes had contributed to these abortions, and suggests that diabetes may be a factor in septic affections of the internal genitalia more often than is generally supposed. After the salpingectomy all symptoms of the diabetes vanished, but the patient succumbed after a few months to extension of the septic peritonitis. He discusses whether it is possible that

the iodoform used after the operation may have contributed to the cure of the diabetic symptoms, or whether it was due to evacuation of the septic foci or to the progressive cachexia. He accepts the latter surmise as most probable, and advises that the possibility of advancing cachexia should be borne in mind when diabetic symptoms vanish after long persistence.

87. **Tuberculosis of Tonsils.**—Among the 3 cases described by Glas were 2 of primary tuberculosis of the tonsils and one of miliary tuberculosis of the tonsils with consecutive general infection by the lymph and blood routes. In all these cases the tonsil was hypertrophied. In one case with a unilateral tonsillar affection, the corresponding vocal cord was involved. Tuberculosis in the tonsils seems to assume the form of a chronic, non-ulcerating sclerosis or to appear as miliary nodules.

90. **Osmotic Pressure and the Organism.**—Kiss emphasizes that the study of osmosis under physical conditions is not applicable to the osmosis under physiologic conditions. He points out that osmotic interchanges occur much more rapidly in the latter than in the former. It is not possible to explain the vital functions on the basis of osmosis, and it is more than probable that as the living cell works with molecules and ions, it utilizes the osmotic forces, guides and transforms them for its purposes in a way beyond the ken of physical chemistry.

91. **Elimination of Bacteria from Organism.**—Noetzel's experiments confirmed the results of others to the effect that in health there is no elimination of bacteria through the kidneys or glands. The bacterial toxins, however, are thus eliminated.

96. **Surgery of Wandering Spleen.**—Sakharoff thinks that if the spleen is more than two or three times its original size, it had better be removed instead of trying to merely fasten it in normal position. He describes a case in which he removed a malarial spleen from a woman of 28, a multipara. The spleen after its removal weighed 960 gm. The hemoglobin gradually increased from 60 per cent. after two weeks to 78 per cent. three weeks later, and the proportion of reds to whites from 115 to 1 at the first examination to 180 to 1 at the second. Her health has continued good to date. He mentions that her appetite became exorbitant for a time after the splenectomy, which phenomenon has been noted by other surgeons in such cases. Typical attacks of malaria also developed eleven days after the operation, but subsided under quinin. This has also been observed by others.

99. **Pseudo-Chylous Ascites.**—Polyakoff describes a case in which the chylous appearance of the ascitic fluid was due to the products of decay of the albuminoids and nuclein, not to admixture of fat.

100. **Gastric Digestion in Chronic Intestinal Inflammation.**—Bazhenoff relates the particulars of 5 cases of chronic enteritis in which special study was made of the gastric digestion. The findings indicate that the subjective sensations of such patients are mainly due to atrophic catarrh of the stomach. It is highly probable that this gastric affection is merely a propagation of the inflammatory process in the intestines. The subjective sensations do not always parallel the anatomic conditions. There may be no symptoms of dyspepsia and yet the wall of the stomach may be completely atrophied. When the gastritis develops secondarily, the prognosis of the intestinal affection may be formulated on the basis of the gastric disturbances, the severer the latter the less chances for recovery of the former. Examination of the stomach digestive functions is also necessary as a guide to diet.

102. **Treatment of Congenital Phimosis.**—Rozhansky recommends local injection of a 2 per cent. warm solution of boric acid twice a day, injecting enough of the fluid to dilate the preputial sac and thus mechanically restore conditions to normal while keeping the parts disinfected.

103. **Study of Epidemic Rubeola.**—Pismenny had occasion to observe an epidemic of 21 cases of rubeola and noticed that it developed in five different ways. In some subjects the eruption was typical, in others it resembled that of scarlet fever; in 8 cases the eruption was *sui generis*, the single patches much larger than usual, deeper colored, isolated, the intervening skin being normal. In 4 the exanthem resembled that of scarlet fever, but the catarrh was that of measles, and in 2 there was no catarrh. He often noticed that contagion from a subject with one form frequently induced the disease in another form. He therefore defines rubeola as an independent contagious disease which runs a course similar to that of mild measles, but occasionally resembles more that of an abortive scarlet fever, and most frequently presents a combination of these two forms. The incubation in his experience was about sixteen days.

104. **Treatment of Malaria with Subcutaneous Injections of Quinin.**—Nevyadomsky advocates the subcutaneous use of quinin when rapid action is desired. He has found this mode of administration peculiarly advantageous for children. In ten to fifteen minutes after the injection of .8 gm. quinin the ears begin to hum. He prefers for these injections a mixture of 10 gm. quinin hydrochlorate and .1 gm. morphin hydrochlorate to 20 gm. distilled water. The deltoid and pectoralis major regions are the best points for the injections, which should be made in the subcutaneous cellular tissue. His experience with thousands of these injections has been extremely favorable, but it has demonstrated that to be effectual the quinin must be injected at the close of the chill or at the commencement of the fever. This rapidly aborts the attack, while injections later, during the sweat or intermissions, do not influence future attacks. He has found that even long-established cases of malaria yielded temporarily or permanently to two or three injections, the cure completed by removal from the malarial region if possible..

106 and 107. **Bulbar Paralysis.**—Muratoff describes in detail a number of cases of what he calls apoplectic bulbar paralysis, with the anatomic findings. Tutyshkin also gives the details of a case of progressive bulbar paralysis with amyotrophic lateral sclerosis.

108. **Influence of Alkalies on Experimental Infections.**—Auerbach was impressed by the fact observed that an alkaline culture medium which was eminently favorable to the growth of bacterial cultures became bactericidal when heated to 108 F. The bacteria died when the temperature was raised to this point. Observation of this phenomenon suggested to him that the high temperature in fever may be a beneficent phenomenon, rendering the alkaline blood more bactericidal. He instituted experiments on animals to establish the correctness of this view, and announces that he found that the blood became less and less alkaline, the more intense the infection.

Endeavoring to restore the alkalinity of the organic fluids by injection of alkalies he found that the animals were able to withstand the inroads of the experimental infection much better than the controls. He concludes from his research that the fever in infections is an important aid in the defensive processes as it confers increased bactericidal power on the alkaline blood and probably also enhances the bactericidal power of other antibodies in the organism.

110. **Initial Lesions in Tuberculosis of Lungs.**—Abrikosoff examined 52 cadavers with circumscribed pulmonary tuberculous lesions and in 8 found the initial modifications caused by the infection. He reproduced them in rabbits by intravenous injection of cultures as well as by direct injection into the bronchi. His research also has established that the tubercle bacilli can penetrate from the bronchial glands into the bronchi even in the absence of lesions in the bronchial walls.

121 (No. 34.) Hospitalsbehandlung af Lungetuberkulose. J. Veje.

111. **Improved Technic of Urethral Injections.**—Engelbreth's article was reviewed in The Journal, page 890, abstracts 109 and 114.

112. **Adiposis Dolorosa in a Boy.**—Gudjohnsen's case was distinguished by the fact that the patient was a young man, and that the symmetrical lipomata were some of them painful and others not. The affection had commenced in childhood and none of the typical symptoms was lacking. In discussing the relations of this affection to myxedema he mentions the entire absence of the lunula unguis in his experience in both affections. He had successfully treated another case of painful lipomatosis by means of six weeks of massage and then two weeks of thyroid treatment, which banished the pains completely. In the present case the fat deposits were so large that the breast measure was 142 cm., almost 52 inches. When the weather was hot the patient did not suffer from pains or hyperesthesia, and consequently felt better in the summer. He was intelligent and slept well, but as his weight was constantly increasing he pleaded for thyroid treatment, which was accordingly instituted. He took two pills a day of 2 cg. of thyroidin with a milk-vegetable diet. After taking fourteen pills symptoms of thyroidin intoxication developed and the patient died eleven days after commencing this treatment. The writer reviews 21 articles that have been published on the subject, including a number by American as well as European authors, besides those of Dercum.

113. **Udder Extract in Treatment of Deficient Mammary Secretion.**—Prip describes 5 cases in which he was able to promote the breast secretion and procure ample nourishment for the child by having the mothers eat cows' udders thoroughly cooked in an appetizing manner. He now makes a soluble powder from the glycerin extract of udders which he proposes to use in future; a single udder, weighing about 4 pounds, makes 13 gm. of the powder. He thinks there is a promising future for this form of organotherapy.

115. **Xerophthalmia in Infants.**—Jensen thinks that a more correct name for this condition would be *ophthalmia ex inanitione*, and that prophylaxis consists in more rational feeding. The prognsis depends on the time when treatment is instituted, and treatment should be dietetic. Local treatment plays but a subordinate rôle.

116. **Puerperal Fever.**—Kaarsberg advocates banishing the curette and using the fingers for removal of the retained afterbirth, etc. He thinks that with appropriate local treatment, applied early, the number of cases of puerperal fever will be materially reduced. He is convinced that the use of the curette instead of the fingers is responsible for many mishaps. In one instance he relates, a septic polyp filling the entire corpus was found postmortem after the uterus had been supposedly throroughly evacuated by the curette in skilled hands.

120. **Ethyl Chlorid Refrigeration Treatment of Lupus.**—Hansen has treated 13 patients with lupus vulgaris by refrigeration with ethyl chlorid. In 8 the affection had commenced within 5 years and in the others had lasted 5 to 9 years and more. The results were a complete cure in 2; apparent cure in 2, and gradual improvement in 2, with improvement but recurrence later in 4. To decide the merits of this method of treating lupus (mentioned in The Journal, page 584) he enquired of Finsen if any lupus subjects previously treated by this means had applied for treatment later to him. He found a record of 62. In 36 of these the refrigeration treatment had been briefly tried and abandoned, as no effect had been apparent. In the remaining 36 it had been energetically applied for three to eighteen months. In only 4 of this number had any actual gain been realized, and it was dubious in 2 of these. In 11 per cent. the treatment had been entirely ineffectual and in 78 per cent. the results had been actually unfavorable. The injurious action was the more marked the lesser the extent of the lesions and the duration of the affection. Hansen warns, therefore, that this treatment must be applied with great caution, as it is liable to do ultimately more harm than good.

130 Om balantidium coli och dess betydelse vid kroniska diarreer. N. Akesson. One case.

124. **Gastric Juice in Tapeworm Cases.**—In 12 out of the 17 cases examined there was no free hydrochloric acid to be found in the stomach and in 5 the acid reaction was very weak. No lactic acid was found, and it was noticed that the stomach emptied itself unusually promptly. In 24 cases of tapeworm in which the gastric juice had been examined, reported by Schaumans and others, free hydrochloric acid was entirely absent in 17. This brings the total proportion to 29 out of 41 cases, that is, 71 per cent. of the entire number of cases in which the gastric juice was examined in persons harboring tapeworms.

125. **Prognosis of Retinitis Albuminurica Gravidarum.**—Ahlstrom describes in detail 7 cases of this affection. In one there were severe symptoms of retinitis in both eyes with detachment of the retina in one eye. A few days later spontaneous abortion occurred at the seventh month, followed by complete restoration of vision. In 2 cases of retinitis vision was much improved after premature delivery the seventh to eighth month. In another patient severe symptoms of retinitis appeared at the second or third month. After premature delivery at the eighth month there was marked atrophy of the optic nerve with almost complete loss of sight. In still another the retinitic symptoms had been of moderate intensity, but vision had been impaired after the sixth month. The pregnancy was terminated by normal delivery. The optic nerve is completely atrophied with amaurosis in both eyes. These cases show that delivery soon after the appearance of the first symptoms of retinitis may be followed by restitution,

while delay may be fatal for vision. The symptoms most important for the prognosis are hemorrhage into the retina and the reflex anomalies in the arteries described by Silex. Whenever one or both of these symptoms are noted in the early stages of a pregnancy it must be interrupted at once, but when not observed until a late stage, expectant treatment is justifiable until there is a prospect of a viable child from a premature delivery. If the patient can not be kept under constant surveillance delivery must be immediate, as also when severe symptoms develop. Further pregnancies must be prevented in women who have once exhibited symptoms of the affection. He describes the particulars of all his cases, including one in which the patient succumbed to eclampsia soon after the symptoms of retinitis had been observed. Another case was lost sight of.

127. **Typhoid Infection of Gall Bladder.**—Jundell gives a careful review of what has been published on this subject, and describes a case personally observed. The patient was a woman of 31, who stated that she had had typhoid fever at the age of 16. She occupied a room with a person who was found to have typhoid, and, herself, exhibited symptoms that suggested typhoid infection on which those of cholecystitis were soon superposed. Operative intervention became necessary toward the end of the fourth week of the typhoid infection and a stone of cholestearin about the size of a hazel nut was found in the cystic duct and typhoid bacilli were cultivated from the gall-bladder secretions. The stone could not have developed in consequence of typhoid infection of the gall bladder, as such a stone is of slow, gradual formation. The stone had probably been pre-existent and had been the predisposing cause for the typhoid infection of the gall bladder.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICE OF MEDICINE. A Text-book for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania. Third Edition, Thoroughly Revised and in Parts Rewritten. With 134 Illustrations, Including Colored Plates. Cloth. Pp. 1,240. Price, $5.50. Philadelphia: P. Blakiston's Son & Co. 1903.

MANUAL OF PRACTICAL ANATOMY. By D. J. Cunningham, M.D. Edin. et Dubl., D.Sc., LL.D., D.C.L. Oxon., F.R.S., Professor of Anatomy in the University of Edinburgh. Volume I: Upper Limb, Lower Limb, Abdomen. Volume II: Thorax, Head and Neck. Third Edition. Illustrated. Cloth. Pp. 605 and 607 Respectively. Price, $5.00. Philadelphia: J. B. Lippincott Company. 1903.

THE DECENNIAL PUBLICATIONS. The Structure of the Glands of Brunner. By Robert Russell Bensley, Assistant Professor of Anatomy. Printed from Volume X. Paper. Price, $1.00. Chicago: University of Chicago Press. 1903.

THE MEDICAL ANNALS OF MARYLAND. 1799-1899. Prepared for the Centennial of the Medical and Chirurgical Faculty. By Eugene Fauntleroy Cordell, M.D. Cloth. Pp. 888. Baltimore: Williams & Wilkins Co. 1903.

TRANSACTIONS OF THE NEW HAMPSHIRE MEDICAL SOCIETY, at the One Hundred and Twelfth Anniversary. Held at Concord, May 21 and 22, 1903. Cloth. Pp. 256. Concord, N. H.: Ira C. Evans Co. 1903.

REPORT OF THE SURGEON-GENERAL OF THE ARMY TO THE SECRETARY OF WAR. For the Fiscal Year Ending June 30, 1903. Paper. Pp. 156. Washington: Government Printing Office. 1903.

New Patents.

Patents relating to medical devices, etc., September 15 to 29:

738887. Ophthalmoscope. Henry L. De Zeng, Philadelphia.
738897. Hydro-electrotherapeutic apparatus. Daniel C. Fisher, Boston.
738995. Orthopedic corset. Franz Haas, Prague, Austria-Hungary.
739083. Massage instrument. John W. Hyatt, Newark, N. J.
739182. Binocular microscope. Frederic E. Ives, Philadelphia.
739098. Combined head gear and ear trumpet. Thomas W. Messenger, Quorn, South Australia.
739200. Splint. John R. Moore, Ironwood, Mich.
738842. Truss. Solomon H. Phillis, Pana, Ill.
739267. Machine for making bandages. Frederick L. Pohlmann, St. Louis.
738848. Atomizing device. Walter Sams, Chicago.
738960. Clinical thermometer shield. Harry Vaughan and J. W. Arrowsmith, Morristown, N. J.
739471. Tray support and closet for physician's tables. William D. Allison, Indianapolis.
739297. Disinfecting device. William H. Dayton, Cleveland.
739670. Vision testing apparatus. Robert K. Grove, Buffalo.
739419. Scarifier tongs. James M. Hyde, San Francisco.
739317. Disinfectant block. Clarence C. Jenkins, Brooklyn.
739336. Invalid bed. William McLennan, Ogdensburgh, N. Y.
739844. Means for promoting the growth of hair. Frederick W. Evans, Columbia, Tenn.
740002. Collapsible stretcher. Kaspar Freuler, Zurich, Switzerland.
740152. Serum container and injector. Thomas J. Lynch, Marietta, Pa.
739941. Manufacturing disinfectants. Carl Spengler, Davos-Platz, Switzerland.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy, week of Oct. 17, 1903:

Asst.-Surgeon C. H. DeLancy, detached from the *Hancock* and ordered to the *Petrel*.

Asst.-Surgeon R. K. McClanahan, detached from treatment at the Naval Hospital, Mare Island, Cal., ordered home, with three months' sick leave.

Pharmacist S. W. Douglass, detached from the Navy Yard, Portsmouth, N. H., and ordered to the Naval Magazine, Iona Island, N. Y.

Surgeon W. F. Arnold, detached from treatment at Naval Hospital, Mare Island, ordered home, with three months' sick leave.

Medical Inspector W. R. DuBose, commissioned medical inspector, with the rank of commander, from June 20, 1903.

P. A. Surgeon C. H. DeLancy, commissioned passed assistant surgeon, with rank of lieutenant, from June 7, 1903.

P. A. Surgeon D. H. Morgan, when discharged from Naval Hospital, Mare Island, granted sick leave for three months.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Oct. 16, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Oct. 4-10, 4 cases.
California: Los Angeles, Sept. 27-Oct. 3, 6 cases; San Francisco, Sept. 28-Oct. 4, 1 case.
Illinois: Chicago, Oct. 4-10, 3 cases; Danville, Oct. 4-10, 2 cases.
Maryland: Baltimore, Oct. 4-10, 1 death.
Michigan: Detroit, Oct. 4-10, 1 case.
New York: New York City, Oct. 4-10, 4 cases; Niagara Falls, Oct. 4-10, 2 cases.
Ohio: Cincinnati, Oct. 3-9, 1 case.
Pennsylvania: Altoona, Oct. 4-10, 1 case; Carbondale, Oct. 8-14, 2 cases; Philadelphia, Oct. 4-10, 11 cases, 3 deaths.
Tennessee: Memphis, Oct. 4-10, 2 cases.
Texas: San Antonio, Sept. 1-30, 12 cases, 1 death.
Utah: Salt Lake City, Sept. 27-Oct. 10, 8 cases.
Wisconsin: Milwaukee, Oct. 4-10, 7 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Aug. 22-29, 3 cases, 1 death.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Sept. 20-26, 4 cases.
France: Paris, Sept. 20-26, 1 death.
Great Britain: Bradford, Sept. 20-26, 8 cases; Newcastle-on-Tyne, Sept. 20-26, 5 cases.
Italy: Catania, Sept. 25-Oct. 1, 1 death.
Russia: Moscow, Sept. 13-19, 1 case, 1 death; Odessa, Sept. 20-26, 1 case; St. Petersburg, Sept. 13-19, 42 cases.
Spain: Barcelona, Sept. 13-26, 4 cases.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Oct. 7-15, 180 cases, 10 deaths; Minera, Oct. 3-12, 50 cases.

YELLOW FEVER—FOREIGN.

Costa Rica: Limon, Sept. 25-Oct. 1, 2 cases, 1 death.

LEPROSY IN THE HAWAIIAN ISLANDS.*

JUDSON DALAND, M.D.

Professor of Clinical Medicine at the Medico-Chirurgical College; Professor of Clinical Medicine at the Philadelphia Polyclinic; Physician to the Philadelphia Polyclinic Hospital.

PHILADELPHIA.

Leprosy has existed in all the islands of Hawaii for many years and was first officially recognized in 1840, and there is general belief that it was imparted from China. As the disease spread rapidly, a board of health was organized in December, 1850, with power to insist on segregation of all persons suffering from this affection, in consequence of which act the malady is gradually disappearing. All leprosy suspects are sent to Kalihi, a receiving hospital near Honolulu, where they are examined by a medical board and all lepers are transferred to Molokai.

Despite the earnest efforts of the board of health, an unknown number of lepers exist in the different islands of Hawaii, which number, however, is steadily decreasing, and is now smaller than at any time in the past. Many of the suspects present conditions rendering diagnosis extremely difficult. This is especially true in certain of the early cases complicated by disease of the skin, such as psoriasis, chloasma, scabies and erythema. Reliance is placed not only on the characteristic changes that are observed in the skin, mucous membrane and nerves, but special importance is attached to the discovery of the bacillus of lepra in discharges from the skin or mucous membrane and also in small portions of excised skin. The bacilli are discovered, usually with great ease, in the skin from the external auricle when this portion of the body is invaded. The recent observations of Boston[1] would suggest the advisability of more frequent and thorough examinations of the blood for the lepra bacillus in suspected cases.

Dr. Jonathan T. McDonald[2] of Honolulu summarizes the diagnostic signs of leprosy in Hawaii as follows:

1. The microscope is the supreme agent of the final diagnosis of leprosy. No patient should be committed to a segregated colony without a bacteriologic demonstration of the disease.
2. Of clinical symptoms, maculæ, chiefly leucodermic spots, are found in 89 per cent. of all cases.
3. The lepra nodule found in 74 per cent. is the one chief distinguishing lesion of skin leprosy.
4. Thinning or complete loss of eyebrows and lashes is present in 63 per cent.
5. Atrophic changes in hands and forearms with retraction and contraction of fingers and enlarged ulnar nerve in 32 per cent., a leading feature of nerve leprosy.
6. The plantar ulcer found in 26 per cent., usually on the ball of the foot.
7. Absorption of phalanges in 16 per cent. with occasional spontaneous amputation.
8. Elephantiasis of hands and feet in 16 per cent.
9. Facial paralysis in 11 per cent.
10. The entire body should be carefully tested for anesthetic areas.
11. Several of the above symptoms can be found in some slight degree at least in every leprous subject.

The Hawaiian possesses a peculiar susceptibility to leprosy. The number of whites that are afflicted are few, and, strangely enough, but few Chinese have been affected with the disease. The census at Molokai from 1866 to 1885 shows 2,997 Hawaiians, 37 mixed Hawaiians, 16 whites, 22 Chinese and 4 other nationalities. It is somewhat difficult to accurately determine the result of segregation by a study of the statistics of the past 37 years because of the great variation in the population in different years, and the extraordinary influx of Chinese and Japanese coolies; further, no accurate census existed as to the number of lepers in the islands in 1865, when segregation was first introduced, and in like manner, despite the earnest efforts of those in authority, the statistics of to-day are only approximate, as many lepers are concealed by relatives or friends so as to avoid being sent to Molokai. The number of commitments during the past ten years shows a gradual decrease. During the year 1900 the number of commitments was 85, whereas in 1891 there were[3] 132. It is the belief of those who have to do with leprosy in Hawaii that segregation has reduced the number of lepers on the island.

I desire to express my thanks to the president of the board of health at Honolulu and to Dr. L. E. Cofer of the U. S. Public Health and Marine-Hospital Service through whose kindness I was permitted to visit the leper settlement Sept. 4, 1902.

The island of Molokai is southeast of Oahu and northeast of Maui. The surface is mountainous; its length is 35 miles and its area 270 square miles. A small peninsula, projecting into the ocean from about the center of the northern coast of the island, was set aside for the lepers by King Kamehameha in 1865 and has an area of 8 square miles. The breadth at the base of the peninsula, where it joins the cliff, is 2¾ miles, at the center 2½ miles, and it measures one mile in length. It is shut off from the remainder of the island by a bold rugged mountain range, extending from the east to the west, having an altitude of from two to three thousand

feet. With the exception of a rough steep trail which is almost impassable, no land communication is possible between the leper settlement and the rest of the island. Communication with the outside world is maintained by a small steamboat, the *Lahua,* which during pleasant

Fig. 1.—Characteristic physiognomy of leprosy.

weather calls at this port semi-weekly. In bad weather it is impossible to make a landing, so that frequently isolation is complete for several weeks. The shore is lined with large rocks, making a rather dangerous approach, and the landing of passengers and cargoes is

Fig. 2.—Leprosy in a girl aged 8 years, showing the characteristic physiognomy of leprosy.

effected by means of small boats. The soil is composed of disintegrated lava and sand, and is made to yield tropical fruits and vegetation by irrigation. An abundance of water is supplied by reservoirs fed by streams from the mountains. As the boat approaches the settlement the appearances of the villages differ in nowise from that of similar villages in other parts of the island. The combination of bright sunshine, cloudless sky, mountainous scenery in close relation with the ocean in which are numerous rocky islands of all sizes, together with luxuriant tropical vegetation and fruits, presents a scene difficult to surpass anywhere in the world.

The census of leprosy in Molokai in 1901 was 1,073. Of the 164 non-lepers, 78 were children of leprous parents, 67 helpers, i. e., those permitted to live and care for the lepers, and the remaining 19 included the superintendent, the physician, the priests, lay brothers, sisters and teachers. The total population is 1,237. Superintendent J. V. McVeigh informed me that there were 861 lepers Sept. 4, 1902, a decrease of 212, of whom about 750 were native Hawaiians. About 600 of the lepers live in Kalaupapa, which is the residence of the medical officer, Dr. W. A. Goodhue; of the superintendent; of the priest of the chapel of St. Francis; of Father Wendelin, the successor to Father Damien, who is in his sixteenth year of service, and of Mother Marieanne, who

Fig. 3.—Tubercular leprosy of the face and ear.

has been in charge of the Bishop Home for Girls with Leprosy for fifteen years and who is assisted by three sisters. At Kalawao, the original settlement, there are about 200 lepers, in which place lives Mr. Dutton, who has been in charge of the Baldwin Home for Boys for seventeen years. The chapel is in charge of Father Joseph, assisted by four lay brothers.

The unselfish labors of these men and women are of the greatest value to the lepers, and I take this opportunity of expressing my appreciation of the excellence of their work and my profound admiration for each of them individually.

It is difficult to imagine a more ideal spot for a leper settlement than that of Molokai, isolated by Nature's barriers, the mountains and the sea; situated within the tropical circle, and possessing a climate admirably suited to those suffering from this disease, and standing in strong contrast to the climatic conditions under which lepers exist in Iceland, Norway and India.

The life led by this community is similar to that of the villagers in non-leprous regions, and they possess

churches, schools, courts and jails. Three baseball teams testify to the popularity of our national game; ping-

Fig. 4.—Tubercular leprosy.

pong is played with enthusiasm, and many devote themselves to fishing, rowing, hunting, horseback riding and driving. Most of the members of the community seem happy and contented, and their love of music is shown by the existence of a village band and singing societies. Although the lepers are cared for at the expense of the government, more than $17,000 was expended in the general store for additional supplies during twelve months. Many of the lepers or their relatives are in possession of moderate fortunes.

The customs of the Hawaiians are such as to facilitate the spread of leprosy, as for example: The use of the family pipe, which is passed from one member to another; the carrying of food to the mouth by means of the fingers, and the general want of cleanliness. I believe that heredity plays a very unimportant rôle in the spread of the disease, as many children born of leprous parents remain free from the disease, more especially if they are removed from their parents at an

Fig. 5.—Macular leprosy.

early age. In 1884 there were 26 children born in the settlement, one or both of whose parents were lepers before each birth. But two developed leprosy, despite the fact that they had lived in the houses of lepers all their lives. This view is supported by Dr. Carleton, who has had 20 years of experience with leprosy in India and has seen 92 children of leprous parents, only two of whom developed leprosy. The majority of observers in Hawaii believe that leprosy is contagious, which view is supported by the observations of Arning, who inoculated Kenan, the condemned criminal, who 2½ years later showed leprous changes in the skin and in various parts of the body, and died of the disease at Molokai. Unfortunately, this experiment is vitiated by the occurence of leprosy in his mother-in-law, his son and his nephew. The historical case of Father Damien, a Belgian, who died of the disease seven years after its first

appearance, and the occurrence of ten cases of leprosy in ten years among non-leprous individuals at the settlement demonstrates the contagiousness of this disease. At the time of this visit no example of a case of this disease contracted in the settlement existed, despite the fact that a number of individuals living in the settlement have been exposed to the disease for periods of 15, 16 and 17 years. The non-infection of a woman who was successively married to three leprous husbands tends to prove that this disease is but feebly contagious. There is a widespread belief among the physicians in Hawaii that syphilis greatly increases the susceptibility to leprosy, and this is believed to be a part of the explanation of the Hawaiian's susceptibility to the disease. The white race enjoys a remarkable immunity and when proper hygiene and good food is secured the Hawaiian's susceptibility decreases.

Fig. 6.—Macular leprosy, with palmar ulceration and absorption of the terminal phalanges.

Leprosy became widespread during the smallpox epidemic in 1852 owing to careless vaccination. It is believed that the disease may be transmitted by the secretions, by cohabitation and by insects, more especially mosquitoes and flies, and that the portal of entry of the bacillus may be the nares, the mucous membrane of which may have become accidentally abraided by the fingernail, or through the skin, which may have been injured; but, in truth, the exact method of entry and transmission of the poison is, in most cases, unknown. Recent observations show that an enormous number of bacilli are found in the nasal secretions when these parts are affected, suggesting that this is an unsuspected source of great danger. Dr. McDonald has examined the mucus from the cartilaginous portion of the nasal septum in a number of cases of leprosy, but he has rarely found the *Bacillus leprœ*. As in other leper settlements the varieties of the disease are the tubercular, anesthetic and mixed; the tubercular variety is most common. Since the establishment of this settlement, from time to time, many forms of treatment have been tried,

Fig. 7.—Leprosy, showing the characteristic plantar ulceration and changes in the fingers.

Fig. 8.—Leprosy, showing the leonine expression, loss of the eyebrows and deformed hands.

but without success. At present the patients are bathed two or three times daily in warm water, and internally

the Goto treatment is employed, the composition of which is a secret. This treatment is apparently beneficial, but is not curative. The tubercular ulcerations are treated antiseptically. There is a widespread belief, however, that the Kausatsu baths in Japan are of decided benefit. Certain cases of leprosy appear to be self-limited, and it is believed that this explains some of the cures that have been reported. The majority of observers believe that segregation prevents the spread of this disease. The following conclusions are deduced from this study of leprosy at Molokai and represent the prevailing opinion in Hawaii:

1. The *Bacillus lepra* is the cause of this disease.
2. This disease is feebly contagious.
3. The Hawaiian is peculiarly susceptible to leprosy.
4. The Caucasian possesses a high degree of immunity.
5. Syphilis predisposes to leprosy.
6. Heredity is a factor of but little importance in the causation of this disease.
7. Segregation prevents the spread of leprosy.
8. The precise manner in which this disease is ordinarily transmitted from the sick to the well has not been proven.
9. There is no cure for leprosy.
10. Benefit may be derived from good hygiene, good food, climate, hot baths and the antiseptic treatment of ulcerative surfaces.

LEPROSY FROM A SANITARY STANDPOINT.*

ISADORE DYER, PH.B., M.D.

Professor on Diseases of the Skin, New Orleans Polyclinic; Editor, *New Orleans Medical and Surgical Journal;* Collaborator, *Lepra Bibliotheca Internationalis;* Honorary Consulting Leprologist to the Louisiana Leper Home.

NEW ORLEANS.

SOME ANCIENT METHODS.

Almost the first knowledge of leprosy carried with it methods for its control. No doubt many diseases were called lepra which did not deserve the name.

The Hebrews, Arabs, Greeks and Egyptians recognized the disease and named it. With each of these peoples treatment was made subservient, while the sanitary measures were often radical.

The Bible (*Leviticus, Numbers* and *Deuteronomy*) quite extensively refers to the lepers among the Hebrews. So true is this that the popular conception of leprosy to-day has been derived from the scriptural relation of it. "And the leper in whom the plague is, his clothes shall be rent, and his head bare, and he shall put a covering upon his upper lip and shall cry 'Unclean, Unclean.' All the days wherein the plague shall be in him, he shall be defiled; he is unclean. He shall dwell alone; without the camp shall his habitation be." (*Leviticus* xiii: 44.)

We read in the same chapter (verse 52) instructions to the priests, "He shall therefore burn that garment, whether warp or woof, in woollen or linen or anything of skin wherein the plague is, for it is a fretting leprosy; it shall be burned in the fire."

"And he shall cause the house to be scraped within round about (chap. xiv: 41-45), and they shall pour out the dust that they scrape off without the city into an unclean place." Clean stones are then ordered and fresh plaster, and if still the disease lurks, "Now he shall break down the house, the stones of it and the timber thereof, and all the mortar of the house; and he shall carry them forth out of the city into an unclean place.

The children of Israel are commanded to cast every leper out of the camp. (*Numbers,* v. 2.) Here and there we find in the Bible archaic methods of cleansing those who may be afflicted, but these are religious rites rather than practical ones, dealing with exhortations, sprinkling with water made sacrificial with the blood of birds or of the proverbial lamb.

The Koran likewise regulates the life of the leper.

These facts are related here with the idea of calling attention to the fact that the problems of sanitary measures in leprosy are not new; that even among primitive people the character of the disease was such as to create a popular fear of it which demanded remedies of prevention.

Historians of leprosy have traced the disease from Syria into Persia, Hindoostan, China, Japan, Australia, New Zealand, Africa, Turkey, Greece, France, Spain, Britain, Germany, Russia, Scandinavia and the Americas.

We find it rising and declining at different periods in different parts of the world, moving gradually from the East to the West and from the South to the North.

Probably limited in the early period of the world to the Orient and to Egypt—

> "High up the Nile mid Egypt's central plane,
> Springs the dread Leprosy and there alone."
>
> —*Lucretius de Natura Rerum.*[1]

The disease spread rapidly through the south of Europe from the second to the seventh century, reaching its acme from the eleventh to the twelfth.

The earliest record of leprosy in Great Britain is found in the year 950; in 1585, by act of Elizabeth, the leper hospital at Sherburn, in Durham, was assigned to other use; during the reign of Edward VI, 1547-1553, most of the lazarettos were empty.

In Scotland the disease was still traceable in the seventeenth century, a leprous woman being condemned in Aberdeen; in 1652, the Lazar House at Greenside, in Edinburgh, was dismantled; in 1742, a public thanksgiving was held in the Shetland Islands to celebrate the disappearance of the disease; in 1798, a native of the Shetlands was confined in Edinburgh.

No particular or extraordinary care was displayed with these victims of an unfortunate disease. From the twelfth to the eighteenth century, each of the countries of Europe was afflicted, France notably having placed on record as many as 15,000 in leprosariums, some traces of which remain to-day in Brittany.

SOME METHODS PRACTICED TO-DAY.

In every country in which leprosy has been found certain methods have obtained for their relief or for the protection of the community. In comparatively recent years the attention of the public has been attracted through the conditions in India, Norway and the Sandwich Islands, in each of which countries systematic methods have been followed and direct results obtained.

As with every revolution of ideas, the natural recognition of the fact that leprosy was increasing through the world created an investigation of the fact. First of all, the extensive report of the British Leprosy Commission in India caused a public apprehension because of the knowledge related that there were some 200,000 victims of the disease in that country.

The Berlin Leprosy Conference, in 1897, followed as a natural consequence, and the results of that meet-

1. Wilson's Text-Book on Diseases of the Skin, 1868.

ing, summed up by a resolution recognizing the disease as contagious, pointing to its undoubted spread and urging the action of governments in the matter, all created an interest which up to the present day is steadily growing. Now, most every government is in line and methods of isolation and prophylaxis have been evolved; Russia has several colonies; France and Germany, Spain and Italy, Greece and Turkey, have all acted on the resolutions of the conference. Japan had already established leprosariums and accounted for 20,000 lepers. The Sandwich Islands have the island of Molokai, and have reduced their lepers to a few hundred in number. Norway, by a radical method of isolation and supervision, has practically eradicated the disease and ameliorated its types. In the Americas, the only hospitals of long standing are those at Tracadie, in New Brunswick, and in Havana. In the former there are about twenty inmates, with only a rare and occasional addition. Havana has 114, most of them among Spaniards, natives and Chinese and almost all of the effete nerve type of the disease. The hospital is excellently managed.

The history of the Louisiana home and of the disease in this state has already been written. Here the types are of the acute forms, undoubtedly endemic and active in character.

The accretion of inhabitants from the Philippines, the increasing intercourse with the western countries, urge a better knowledge of the disease and an appreciation of methods. The United States government has already established points for the isolation of lepers in the Philippines and on the island of Guam.

THE COMMUNICABILITY OF LEPROSY.

Notwithstanding the fact that the lepra bacillus is found in all cases of leprosy in which there are evident lesions of the disease, that the bacillus is frequently in the nasal secretions, that it has been found in the earth from the graves of lepers, that it has been found in the rooms where lepers lived, that it has been found on utensils used by them, there are those who contend that the disease is not contagious. Their argument is based on the fact that Koch's law is not fulfilled, i. e., that the disease is not propagated in animals nor in other subjects, who, inoculated in turn, transfer it to others. I believe we can dismiss these antagonists because of their purely technical position in the face of other circumstantial and positive evidences. To wit: Leprosy spreads in any community in which it is introduced; it spares neither old nor young; it may be selective of race, but it occurs almost directly in close community life; it occurs in families, and has not been proven hereditary; it frequently attacks the children before the parents; there is almost always a history of exposure either direct or indirect and, if sought for, communication of the disease from person to person may be traced.

The shortness of this paper prevents the detailed relation of cases, but enough have been recorded elsewhere to bear out the argument.

Opinion to-day classifies the degree of contagiousness in leprosy. Formerly it was believed that contact with the unbroken skin of a leper would produce the disease. Popular fear created the impression that looking at a leper, being in his presence, was sufficient; to-day, the consensus of opinion carries the belief that the nasal and buccal secretions, together with those of the generative apparatus, are the most frequent sources of the spread of the disease. This is borne out by the fact that the tubercular types of leprosy nearly always show the first signs on the exposed parts of the body, face and hands, and that early in the disease the nasopharynx presents tubercles.

As a protagonist for the non-contagiousness of the nerve type of the disease, Dr. Ashburton Thompson suggests that these cases present no lesion in which the bacillus may be found, and that they are rather the types of the effects of the bacillus than of an acute disease. He has repeatedly examined the macules and nerve sheaths, together with the nasal passages, with negative results so far as the bacilli are concerned. Dr. Thompson has many followers. The writer is in line up to a certain point, but experience has shown that in these cases, when neglected, the course is the same as with other types of the disease.

Within the last five years no less than six cases of nerve leprosy have been treated in the clinic for nervous diseases at Charity Hospital, in New Orleans, as syringomyelia, subsequently being referred to me when eruptions appeared. Of these cases, three presented tubercle lesions, the others being seen in time to prevent the granulation changes.

METHODS OF PROPHYLAXIS FOR INDIVIDUAL AND COMMUNITY PROTECTION.

The writer is comparatively a young man, and in his relation to the disease of leprosy his experience has been just a decade. In that time, however, the opportunity has been afforded of the observation of the disease among all classes of people: The beggar, the indigent and careless negro, the workman crippled by the disease, the butcher, the baker, the cook, the clerk, the tradesman, the merchant, the housewife and the well-to-do.

Within these ten years have been noted instances of the disease spreading from father to child, from daughter to mother, from sister to sister, and many others occurring with no evident family relation accounting for the disease.

The evidence has been sufficient to thoroughly impress the fact that the disease does spread and that it occurs in individuals in Louisiana who have either lived in affected communities for periods of not less than ten years or else they were born, reared and have always lived in the state.

Cases have been noted which have lived in comparative intimacy in the family life with no evidence of the spread of the disease—as yet.

The subject of prevention in leprosy has been thoroughly discussed both from the standpoint of the individual and from that of the public, and whatever opinion the writer may have must, of course, repeat in large measure the views of those who have gone before. This may be stated briefly under two heads:

The Individual.—Either the victim of leprosy should be segregated with those of like condition or else, if he lives in his own family, he should be given a separate room; should have his meals alone; should wash his own utensils and should have his laundry boiled separately. I believe that this is difficult, because, even when the family are aware of the disease, they become careless in the family relations.

The Public.—The public care of lepers provides: (*a*) segregation under systematic methods which should consider (1) the segregation of the sexes; (2) some arrangement by which the trophic or nerve type should be entirely separate from the tubercle type or skin leprosy, because it is my belief that there is no reason why a leper with nerve leprosy should not acquire fresh lesions from

infection by a new contagium carrying the leper bacilli, found so freely in the tubercle type. Heretofore leprosy has been held as incurable and the simple diagnosis of leprosy has been sufficient to condemn a victim, irrespective of the type and he is doubly condemned if he is exposed to fresh infection while he is trying to get well. (*b*) Particular methods of sanitation should obtain. No institution pretending to care for lepers should be without the fullest equipment for bathing facilities, both medical and plain. Water in leprosy is as potent in its prophylaxis as it is for remedial use.

One word in conclusion. Educate the profession and the public regarding the disease. Let them know what leprosy is, not a colored impressionist's picture, but the truth of its physical and moral characters.

Unfavored of God's kind,
And set apart, a curse;
A living death for men to pity,
As they shudder at the worse
Than sin, or pain, or shame
Of *It;* for can a name
Be borne by one of these?

Not spotted white, nor snowy clean,
As Bible tales remark it;
But, bursting through a boiling skin
Of lumps and bumps, a thickened mass
Of bronzed and blackened human kin,
With here and there a spot of brown
Or lighter hue, while over all a tint of red
By Nature's thrown, as if to hide the frown
Which masks the soul of those
Who bear the burden of the blight.

Nor king nor serf the scourge hath spared,
And as the ages into æons run,
These sightless, voiceless human parodies
Will breathe the tones of the Unblest;
Accursed by all, marked by Fate,
As victims of the great Unrest,
The Morbid in the True, too late
To save their souls for better things.
And so the fell decree makes members
One by one to fall, until at last
The end finds semblance only of a past.
A trace alone of kinship to the race
Which bore it, in this, a mass
Of tissues, human once, but now
Distorted, framed and bound in shapes
Fantastic in their frightful symmetry,
And shorn of everything but form.

124 Baronne Street.

DISCUSSION.

Dr. G. T. Swarts, Providence, R. I.—The subject of leprosy is a matter that does not come very prominently before our health boards, and yet our experience in Rhode Island leads me to believe that it would be well for all our state health officers to familiarize themselves with the customs in vogue in the states where lepers are found in respect to isolation of the patient. In our principal hospital in Providence there appeared a case of what we called skin disease, ulcers on the foot and a mottled appearance of the skin. There being anesthesia in the lower limbs and the arms we thought that our neurologist should have the case in his department. However, the interne, becoming suspicious at the mottled skin, and thinking possibly it might be a case of leprosy, referred to the books and discovered that anesthesia is a common condition of leprosy, and considering the ulcers at the base of the big toe, he jumped at the conclusion that it was leprosy. To make sure about it he obtained the nasal secretions and there found the bacilli of leprosy. That, of course, made the diagnosis complete. That man had been living in the city for five years without our suspecting that he was a leper. He had abnormal thickening of the face, but you could find the same condition in any sailor on our coast. The question with us was what to do with the man. Should we isolate him as we do in smallpox cases, or should we give him the freedom of the city? We wrote to Dr. Dyer and others familiar with the subject, and obtained valuable advice. In the meantime, unfortunately, the man, finding out what the disease was, asked for his clothes and disappeared. We have not been able to trace his whereabouts since. Had he remained with us we would have been worried to know what to do with him. We, of course, wanted to protect ourselves, and yet not impose on the individual. That is the reason this paper was requested of Dr. Dyer, so as to put the various health officers in position to know what to do in cases of this kind. You know that the public, immediately on hearing of a case of leprosy, imagine there is a scourge of the disease, and demand extreme precaution from the health officers for it.

Dr. W. H. Sanders, Montgomery, Ala.—Could you trace the infection?

Dr. Swarts—He had resided in South America for twelve years before he came to us. He had lived for years with his wife, who was not affected, so far as we know. She has since died, of some other disease. A daughter, aged about 12 years, did not seem to be affected. Therefore, the question arises as to whether there is any danger of infection. The nasal secretions were found to be saturated with these organisms, which, it seems to me, could have been communicated to any susceptible soil.

Dr. H. M. Bracken, Minneapolis—The conditions in Louisiana and those in Minnesota are supposed to be quite different. As I understand it, all, or nearly all, of the lepers in Louisiana are American born or residents of the United States for some time. Is not that so?

Dr. Dyer, New Orleans—The list of cases which I submitted to the Berlin Leprosy Conference have either lived in Louisiana for at least ten years or were born here; and the same statement is true of all cases coming to my knowledge since I made up that list. I never saw a Chinese leper in my life, and only one Scandinavian; he was sent back by the same ship on which he came.

Dr. Bracken—There were some Norwegians who came to our state with the idea that change of climate would give them an opportunity to recover. There were a considerable number of lepers in Minnesota fifteen or twenty years ago, but only a few now, and the position was taken that in Minnesota there is no danger of the disease being transmitted. There was no record of any American-born leper in Minnesota until within the past two years. I know of three now, but they are all of Scandinavian parentage. Two of them were brothers. There were no lepers in the family, and it is thought that the first brother became infected from a nurse girl. The third case I have in mind is the son of a leper. Under the conditions prevailing in Minnesota we have thought it only necessary to give the family advice as to how to care for the leper, in the shape of food, clothing, etc., without separating the subject from his family entirely. So far as I know, there has been no spread of the infection, except in the cases mentioned above. Minnesota is watching to see what the nation will do, because we feel that the disease can be better dealt with by the federal government than by the state. Of course, lepers who are poor are taken care of by the counties and are isolated.

Dr. Sanders—How many lepers are there in Minnesota?

Dr. Bracken—I know of thirteen or fourteen. They keep dying off and new ones coming up. So far as I know there were never more than twenty-eight or thirty in the state at one time. When I became secretary of the State Board of Health there were twenty-two, but some of these have died. Wisconsin used to have some lepers, but the state is getting older now, and they only have two or three. Iowa also has a few. There are also some isolated cases in North Dakota.

Dr. J. M. Lindsay, Havana, Cuba—Do you know the history of the American soldier that got the disease in the Philippines?

Dr. Bracken—I do not.

Dr. T. T. French, Honolulu—The history of leprosy in Hawaii is interesting from a sanitary standpoint. The popu-

lation there has always been small and compact. There are no densely settled places, nor are there any sparsely settled ones. The country is so remote that commerce and intercourse with other countries have been very much restricted. There are a large number of Americans living in close proximity to the natives, and the country has a larger proportion of physicians than such small countries usually have—and a good many very able ones, too. Fifty years ago there were no lepers there. Thirty years ago one in each thirty Hawaiians was a leper. There is no absolute record with regard to the first case among them, but there were a number of Chinese imported, and they undoubtedly brought the disease. There was no word in the native language for leprosy until the disease appeared, and it is now called "mai pake," meaning "Chinese sickness." There is some dispute as to the time and place when that name was first given to it, but it is universally used by the natives, and I judge that the disease comes by the name honestly, because, as I say, a lot of Chinese were imported to work on the sugar plantations, and, of course, they brought the leprosy with them. About thirty-five years ago, fifteen years after these Chinese came with their disease, lepers were isolated on the island of Molokai, and a colony established there. We noticed that the disease kept on spreading after the establishment of that colony, until it reached its maximum, about thirty years ago. Since that time it is claimed that the disease has diminished, but my opinion is that it has probably remained about the same, because the population has been reduced, and while there are about 800 lepers in this colony, there are about 400 at large, making an aggregate of 1,200. Therefore, the effect of segregation has evidently been to check any spread. The reason for not isolating cases in the early stage was simply for fear that a correct diagnosis had not been made. When cases were sent to the board of health for examination they were not willing to segregate them, so they were pronounced leper suspects, and sent back to their districts to be kept under surveillance and make periodical reports to the local officers. In that way they were allowed to linger in the district a long time, and conditions got worse. I think that is the way the disease has been allowed to keep on and smolder as it has.

DR. ISADORE DYER—Referring to the point made by Dr. Swarts, I had a case of a girl who had been treated by Dr. Blanc some seven years previous to her calling on me. She bore no evidence of leprosy beyond a true trophic ulcer on the ball of the big toe. I did not examine it bacteriologically. The father of the girl was a typical tubercular leper and a recent case. It was a matter of history that the girl had been infected at least seven years before she came to me. The father was an Irishman who had lived here for years, and the girl was about 22 years old when I saw her.

DR. T. T. FRENCH—As to leprosy being hereditary, there is a home in Honolulu for the non-leprous children of lepers. The parents often object to their children being taken away, but there is generally an average of twenty or twenty-five girls kept there until they are 18 or 20 years of age. Only one case of leprosy has ever developed there, though we have many children of two leprous parents. After they leave the home you can not tell anything about them, but when you consider that they stay there until they are about 20 it seems to me that is a pretty strong argument against leprosy being hereditary.

Hemostatic Action of Ovarian Extract.—The tendency to hemophilia seems to belong exclusively to the male sex. It may be transmitted from grandfather to grandson, remaining latent in the mother. This fact and the frequent observation of severe epistaxis in young girls approaching puberty, when the ovarian functions are not yet fully established, suggested to Dr. S. Zavadier of Fouriesburg, southern Africa, that the ovary might possibly be the organ that inhibits the tendency to hemophilia and thus renders women exempt although able to transmit the tendency to their offspring. In a recent severe case of hemophilia, rebellious to all other known measures, he finally administered ovarian extract and with the most encouraging results. The *Semaine Médicale* mentions in quoting his communication that Dr. E. Fuller of New York recently proposed thyroid treatment for the same purpose.

FIXATION OF THE PROLAPSED KIDNEY.*

AUGUSTIN H. GOELET, M.D.
Professor of Gynecology in the New York School of Clinical Medicine; Gynecologic Surgeon to the Metropolitan Hospital.
NEW YORK.

That so many modifications of this operation have been made since it was originally attempted by Hahn in 1881 is the best evidence of the necessity of correcting prolapse of the kidney by permanent fixation, despite the opposition to operative interference in some quarters by those who favor belts and corsets. It suggests also the possible inefficiency of many of these procedures. Almost every well-known surgeon has some special technic of his own, but few of them have many followers. It is my purpose in submitting here a technic of my own, which I have employed now for nearly three years and

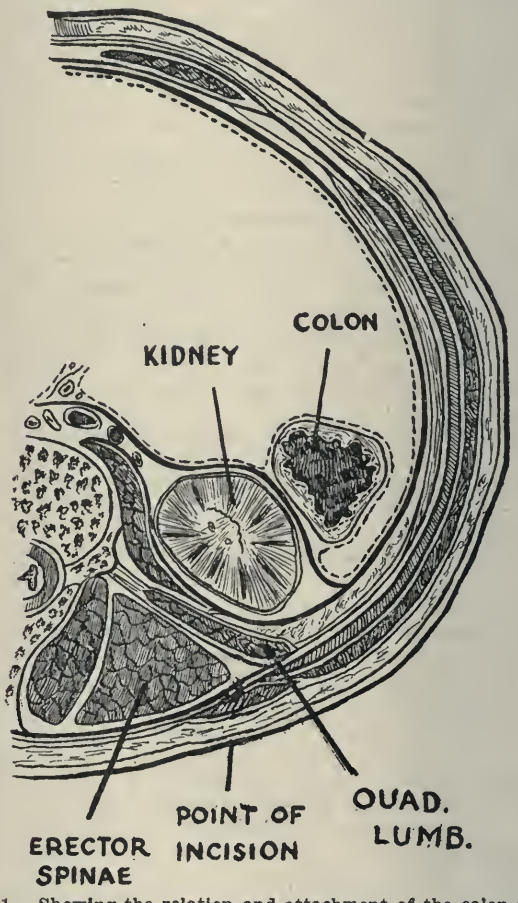

Fig. 1.—Showing the relation and attachment of the colon to the kidney, and the relative location of the muscles encountered in reaching the kidney through the vertical lumbar incision.

have found uniformly successful, to point out some of the causes of failure with this operation and show how it may be made successful and satisfactory.

The inadequacy of belts or corsets or any other form of external support when the kidney has descended below the border of the last rib in front so its upper pole may be palpated, is more readily appreciated if we consider what such support does. It is only a substitute for relaxed abdominal walls and the pendant abdominal organs, but in only a small proportion of these cases is the abdominal wall relaxed. The kidney is normally a movable organ, its normal range of mobility downward being from an inch to an inch and a half on deep in-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

spiration, and it is restrained from further descent only by its surrounding fat and the vessels entering the hilum. To some slight degree additional support is afforded at times by the intestines—the colon in particular, to which it is attached on its anterior surface. This attachment of the colon, however, is one of the chief reasons for its displacement, for when the colon becomes distended it drags on the kidney and the traction is invariably downward when the waist is constricted by corsets or clothing, the distended bowel, as is well known, being crowded below the waist line.

Belts and corsets are not, however, entirely without value, and are useful in the earlier stages of mobility before the kidney has descended below the rib in front, to prevent or retard further descent, and also after operation to support the abdominal organs when necessary and give the patient a feeling of greater security. I believe, however, they are of little or no value in preventing recurrence of the prolapse when the operation for securing fixation of the organ has been properly done. On the other hand, belts and corsets, beside being inadequate, are positively injurious when adjusted to support the kidney after it has descended below the border of the rib because of the irritation to the kidney from the pressure exerted on it. My views on this point correspond with those of Henry Morris of London, who has also had abundant opportunity for careful observation.

The disadvantage, then, of belts or corsets adjusted to support the kidney when it is prolapsed below the ribs in front, is that the pressure necessary to afford effective support will certainly provoke undesirable irritation and eventually lead to serious inflammation in or about the kidney.

INDICATIONS FOR OPERATION.

Prolapse of the kidney to the third degree or beyond, that is, when it has descended below the border of the last rib in front and its upper pole can be palpated when the patient is in the erect position, may be considered sufficient indication for operation because:

1. Prolapse of the organ to that degree permits abnormal mobility and is not conducive to health or comfort though it may not produce intolerable symptoms at first.

2. The position of the kidney when the patient is in a sitting or the erect position interferes with the draining off of the excreted urine, either because of flexure of the ureter or compression of the ureter by the kidney which overlaps it and presses backward on it when the abdomen is constricted by the corsets or clothing.

3. Its circulation and function are seriously impaired by the displacement, and inflammation of its structure frequently results.

4. The kidney when prolapsed to this extent overlaps the ovarian vein as it ascends along the spine, compressing it and retarding the return circulation from the pelvis, thus being a frequent cause of pelvic disease.

If the opposite kidney is sufficiently movable to descend on deep inspiration so that half of the organ can be palpated, it should be fixed at the same time as its fellow to avoid the necessity of subjecting the patient to a second operation, which would be inevitable, because when the kidney is movable to that degree the mobility invariably increases, the degree of descent being progressive. I have several times been obliged to repeat the operation on the left kidney a year or two after fixing the right when either the patient or her physician has opposed a double operation or when the degree of descent of the left kidney at the time of the first operation was not considered by me sufficient to warrant operation.

Nephropexy is justifiable in hysterical and neurasthenic patients because it is an anomalous condition that should not exist; it is a constant source of irritation; it impairs the health of the patient and may operate as a cause of these nervous disorders by acting as an internal traumatism.[1]

PREPARATION OF THE PATIENT FOR OPERATION.

In addition to the usual preparation of the field of operation to secure asepsis, there is some general preparation of the patient that is essential for success. It is useless to delay operation in an attempt to build up a patient whose health is impaired in consequence of this condition, but very much can be accomplished that will be of material aid at the time of operation and during convalescence by correcting digestive disturbances beforehand and securing normal functional activity of the liver, and it is well worth the delay required.

It is very necessary to avoid excessive vomiting following anesthesia because of the strain it puts on the freshly attached kidney, and this can only be obviated by relieving the digestive disturbances beforehand by careful dieting and medication and restoring normal activity of the liver. At least a week should be consumed with such preparation and in cases of long standing from two to three weeks' preparation will insure a smoother convalescence.

Fig. 2.—Showing position of the patient on the table, ready for operation, with the air pillow in position under the abdomen.

OBJECTS TO BE OBTAINED IN NEPHROPEXY.

1. Permanent fixation of the kidney in its normal position.

2. Complete separation of the kidney from its attachment to the colon and duodenum in front to obviate subsequent dragging on it.

3. Avoidance of injury or mutilation of the kidney.

4. Avoidance of mutilation of the patient by a disfiguring scar or injury of the structures penetrated in gaining access to the kidney.

5. Cure of the symptoms or conditions caused by the prolapse.

TECHNIC OF THE OPERATION.

The patient when anesthetized is turned over on the abdomen and a roll or air-pillow eight inches in diameter is placed under the abdomen which flexes the spine, increases the costo-iliac space and forces the kidney up into position. A vertical incision is made through the skin and fat down to the first layer of muscles beginning just below the last rib and extending downward along the outer border of the erector spinæ muscle for about three and a half inches. This will be about three to four fingers' breadth from the spine according to the

1. Albarran, quoted by Henry Morris.

width of the back. The sheath of the erector spinæ should not be opened, but the fibers of the latissimus dorsi are drawn aside with blunt hooks and the lumbar aponeurosis is divided with scissors to the limit of the wound above and below, exposing the quadratus lumborum muscle beneath. Bleeding points should be caught with hemostatic forceps and tied before proceeding.

Fig. 3.—Showing location of the vertical lumbar incision on both sides.

Broad retractors are now inserted and the quadratus lumborum muscle is drawn to one side toward the spine, exposing beneath the transversalis fascia. This fascia is divided with scissors to the extent of the wound above and below, exposing the fatty capsule immediately beneath it. In dividing this fascia it is important to avoid the iliohypogastric nerve, which crosses obliquely in

Fig. 4.—Author's blunt hooks (reduced in size) employed for separating muscles in the direction of their fibers in gaining access to the kidney after incision through the integument and fat.

front of the quadratus lumborum muscle and to include it in the retractor on the spinal side of the incision.

The kidney is now located by inserting the finger and sweeping it around over the surface of its fatty investment. The fatty capsule is then opened with scissors well up toward the upper angle of the incision and well over toward the spine to avoid opening into the peri-

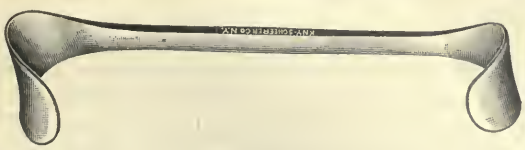

Fig. 5.—Author's broad universal retractors (reduced in size).

toneal cavity or wounding the intestine which bulges up at the lower angle of the wound, and the incision is extended in a vertical direction downward on the finger as a guide. The margin of the fatty capsule on each side is seized with T forceps and traction is made on them to bring the kidney up into the wound and the work of detaching the fatty capsule from the kidney is begun. In adjusting the T forceps to the outer margin of the fatty capsule care must be taken not to include the intestine or peritoneum.

If the peritoneum is inadvertently opened in exposing the kidney no harm will result if it is immediately closed by a running suture of fine catgut. The incision then to expose the kidney is to be made further over toward the spine. This accident should not occur if the kidney is in position and is properly located before the incision into the capsule is made.

In detaching the fatty capsule from the kidney the finger should be used, aided by blunt scissors where particularly resisting bands of adhesion are encountered. The lower pole of the kidney is to be freed first, then traction on the detached fatty capsule will bring it up into the wound. If the kidney can not be delivered through the incision by traction on the capsule the patient is rolled downward on the air-pillow under the abdomen, which brings its pressure more directly on the border of the ribs and forces the kidney up into the wound.

Traction now downward on the kidney grasped with a gauze pad held between the fingers and traction on the fatty capsule at the same time will succeed in delivering the kidney through the incision on the surface of the back.

The fatty capsule is then completely detached from the kidney around both poles and on each side back to

Fig. 6.—Author's kidney needle (actual size) for inserting the sustaining sutures under the fibrous capsule.

the hilum. Complete detachment of the colon and duodenum in front is thus secured, and behind the kidney is left bare of its fatty investment for subsequent adhesion to the solid structures of the back.

It is not always necessary to deliver the kidney through the incision in order to detach the fatty capsule and insert the sustaining sutures, and it consumes more time. When, therefore, complete detachment can be accomplished without doing so this part of the technic may be omitted.

The pelvis and ureter are now carefully explored with the finger for stone, which should be removed if found before proceeding with the operation.

The fibrous capsule is not detached from the kidney nor is its surface scarified. Firm adhesion of the kidney with its fibrous capsule intact can be secured invariably if the kidney is held immovably in contact with the opposing structures for a sufficient length of time. To accomplish this, however, the suture material employed should be one that does not stretch or become absorbed, and it must be inserted and tied so that the suture loop does not become loosened by cutting into the tissues. We have in silkworm gut a material that will meet these requirements, and to render it pliable it is boiled and preserved in a 3 per cent. solution of lysol. My record of 159 nephropexies by this method without a failure to secure permanent fixation shows conclusively that stripping off the fibrous capsule or further mutilation of the kidney as by sutures which transfix the parenchyma is quite unnecessary.

The sustaining sutures, two in number, are inserted on the posterior aspect of the free border of the kidney. One, the lower, is inserted at about the junction of the middle and lower thirds of the organ and the other at about its center or midway between the poles. The

suture is threaded into small, full-curved needles one inch long, and is bent sharply at the eye of the needle and twisted tightly to avoid tearing the capsule as it is drawn through.

The needle is inserted first from above downward in a direction somewhat obliquely inward to the long axis of the kidney, and penetrates only beneath the fibrous capsule for about half an inch in length and the suture is drawn through; then it is inserted transversely a little below the point of exit of the first insertion, penetrates beneath the fibrous capsule only for a distance of about half an inch and the suture is drawn through, and then again inserted obliquely from below upward at a point opposite the first insertion about an inch from it and the suture is carefully drawn through. The needle is removed and the two ends are clasped temporarily with a hemostatic forceps. The second suture is inserted in a similar manner just above the first. (See Fig. 7.)

Inserted in this manner the suture will resist very considerable strain on it without cutting out—very many

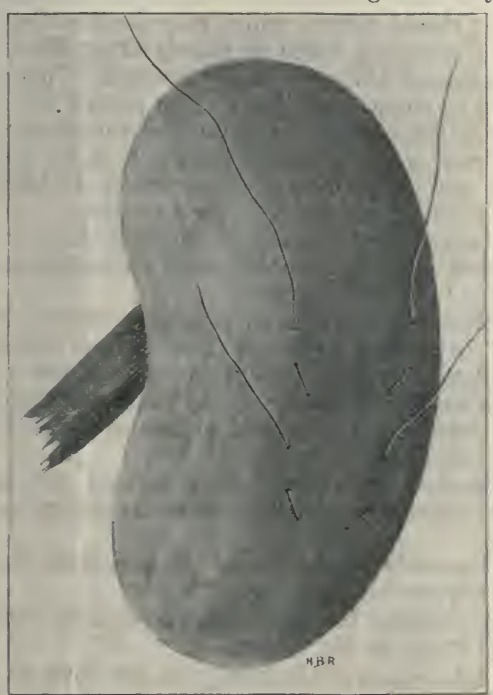

Fig. 7.—Author's sutures for fixing the kidney. Showing their location and method of insertion under the fibrous capsule, which is left intact.

times more strain than the transverse suture, which penetrates the parenchyma, or any suture inserted through the detached fibrous capsule, and it does not mutilate. The stability of this suture seems to be due partly to the exposed portion of the loop left on the outer surface of the capsule and partly to the direction of the traction which is borne mainly by the transverse insertion of the loop and which is in a direction parallel to the capsule or surface of the kidney and not at right angle to it, as is the case with all other sutures employed for fixing the kidney.

Before returning the kidney into its normal position the redundant fatty capsule behind is trimmed off with scissors or torn off, and that in front also, but here care is necessary to avoid encroaching on the peritoneum or bowel. The fat about the lower pole is not removed.

If the kidney has been delivered through the incision it is now replaced and the ends of the sutures are carried through all the structures of the back and brought out on the surface at the upper angle of the incision—a long, curved perineal needle with eye near the point being utilized for this purpose. The sutures are tied over a fold of several layers of gauze placed lengthwise to the incision. This prevents the suture from cutting through the skin and loosening of the loop. When tied these sutures bring the kidney up into its normal position with its upper pole under the ribs.

A gauze drain is now packed around and under the lower pole of the kidney, forcing back the fat that has not been removed and the bowel which bulges up below the kidney, and the end is brought out at the lower angle of the wound.

The wound is closed by uniting the divided superficial fascia with a running catgut suture and the skin with the subcuticular suture. A bountiful supply of loose aseptic gauze is applied next the wound and over this is placed a thick pad of absorbent cotton covered with gauze, and this is held in place by adhesive strips and a binder encircling the body.

AFTER-CARE OF THE WOUND AND OF THE PATIENT.

Twenty-four hours after the operation the dressing which will be found soaked with drainage from the wound should be removed and renewed, but the wound is

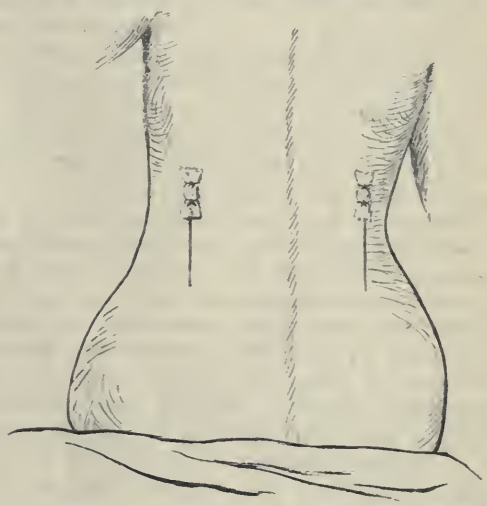

Fig. 8.—Showing position of the gauze pads at the upper angle of the incision, with the sustaining sutures tied over them.

not otherwise disturbed. At the end of forty-eight hours the gauze drain is removed and the dressing renewed. After this the dressing is removed whenever necessary.

The sustaining sutures are not removed until the twentieth day, the day before the patient gets out of bed. The exposed portion of the loop of each suture on one side of the gauze cushion is cut with sterile scissors and the suture pulls out readily, adhering to the gauze when it is lifted off. A simple dressing of gauze is applied afterward.

When renewing the dressings the patient should be turned on the side operated on, and if both kidneys have been fixed at the same time she should be turned on the side that the displacement was greatest.

During the first twenty-four or forty-eight hours the patient will complain of considerable pain in the back and the temperature may rise to 101 or 102 degrees, but both pain and temperature will subside when the drain is removed. An eighth of a grain of morphin may be given hypodermically during the first twelve hours if the pain is sufficiently severe to require it, but it should be avoided when possible. In those cases where drain-

age has not been employed the pain has been quite as severe, so it does not seem to be due altogether to the presence of the gauze, but rather to the manipulation of the structures of the back at the time of the operation.

Vomiting should be avoided if possible, and for this purpose nothing acts so well as oxalate of cerium, in doses of from seven to ten grains, repeated in three to four hours. The stomach should be kept empty for the first twenty-four hours, nothing being given during this time but hot water in small quantity at a time. If thirst is annoying, an enema of normal saline solution should be given. The bowels should be moved on the second day after operation and every day thereafter. Careful dieting will be necessary in some of these cases to keep in abeyance digestive disturbances which may continue after operation, and functional activity of the liver should be preserved throughout convalescence.

During the period of confinement to bed, which is three weeks, the patient should be kept strictly on her back if both kidneys have been operated on. But if only one has been fixed she may turn on the side of the affected kidney. The reason for this is obvious, as it prevents the kidney from dragging on the sutures.

When the patient gets up she should wear an elastic abdominal belt which reaches from the pubes to the level of the lower border of the ribs. This should be worn for at least six months and she should avoid exertion of any kind that would put unusual strain on the kidney. If she has worn corsets before they may be resumed after a month, but the belt must be worn as well, and they must be adjusted so they will be snug over the lower abdomen and hips and loose at the waist and above.

One thing that must not be lost sight of is the digestive disturbances or other disordered conditions that the displaced kidney may have caused. These may not subside unaided after fixation of the kidney, and the patient should be kept under observation and treatment until a fair state of health has been restored. Removal of the cause does not always cure immediately disturbances that have become chronic. Some of these patients show improvement from the beginning of convalescence and require no further attention after they are able to get about again, but others may require attention for some time after.

THE CAUSES OF FAILURE AFTER NEPHROPEXY.

There are many reasons why this operation may prove either a failure or may fail to afford anticipated relief, and to make them more comprehensive they are arranged as follows under separate heads, viz.:

1. Delay in operating until the kidney has become seriously disabled or an incurable nephritis has developed.

2. Delay in operating until the health of the patient and digestive apparatus are seriously impaired or incurable.

3. Unusual and irreparable ptosis of the abdominal organs as a complication of nephroptosis. In these cases, however, since the kidney is many times the most important element of the enteroptosis, fixation of this organ and support of the others by belt places the patient in a comparatively comfortable condition.

4. Failure to prepare the patient properly for the operation.

5. Failure to detach completely the fatty capsule from the kidney—that on the posterior surface to permit the kidney to come into contact with the structures to which it must become adherent, and that on the anterior surface so as to separate the attachment of the colon and duodenum on the right side and colon and pancreas on the left. Unless this detachment of the bowel from the kidney is complete there will still be dragging on the kidney, which, if it does not pull the kidney away from its attachment, will give rise to annoying pain and other symptoms.

6. Improper insertion of the sustaining sutures whereby they either tear out completely or cut through the fibrous capsule and permit mobility of the kidney before it can become permanently attached.

7. Failure to immobilize the kidney until it can become permanently attached by adhesive inflammation, either by improper tying of the sutures or the use of suture material that stretches when it becomes softened after being buried in the deep tissues of the back or absorbs too quickly, or by fastening the retention sutures to the soft structure only which yields to the constriction of the suture allowing the loop to loosen.

8. Too early removal of the retention sutures.

9. If the remaining fatty capsule is permitted to become interposed between the kidney and the structure to which it should adhere, which may occur either at the time the wound is closed or shortly after, the stability of the attached kidney is greatly lessened. This may be obviated by employing a gauze drain packed around and under the lower pole. An additional advantage of this gauze drain is that it lessens the strain on the retention sutures and prevents the accumulation of blood and serum about the kidney after the operation.

10. Delaying the removal of the gauze drain too long after operation, which would permit accumulation of the discharge back of the gauze.

11. Excessive vomiting or coughing shortly after operation may loosen the kidney from its fresh attachment.

12. Permitting the patient to turn on the opposite side too soon after operation may cause detachment.

13. Permitting the patient to assume the erect position too soon after operation.

14. Neglect to adjust proper support for lax abdominal walls after operation when the patient gets out of bed.

15. Too early resumption of the corsets or their improper adjustment.

16. Permitting too early such exertions as would put unusual strain on the kidney.

17. Attachment of the kidney too low down in an abnormal position whereby it would be constricted and irritated by the pressure of the clothing at the waist or by the corsets.

18. Neglect to correct by remedial measures after operation derangement of the digestive apparatus and other conditions caused by the prolapse.

RESULTS.

When the kidney is properly and permanently fixed in its normal position and the conditions caused by the displacement have been corrected, the result of the operation will be satisfactory. We must not, however, lose sight of the many possible contingencies that may interfere with a final successful issue and lay undue stress on the correction of the displacement alone.

Objection to the operation on the score of its mortality does not hold, for I have done 159 nephropexies on 126 patients, in 33 of these fixing both kidneys at the same time, without a death and without a failure to secure permanent fixation. Cure has resulted in all cases that I have been able to trace in from two to twelve months after operation. In one case only was the operation followed by an unpleasant complication—iodoform pois-

oning resulting from the use of 10 per cent. gauze freshly prepared with ether and alcohol. The patient, however, made a good recovery and was out of bed at the usual time.

It has been objected that the risk of an operation is not warranted in these cases when the symptoms may be relieved by a properly adjusted belt or corset. Estimated from the above report the operation has no mortality, hence there is no risk entailed, and temporary relief of symptoms does not mean a cure. Neither the corset nor the most perfectly adjusted belt will replace the kidney or hold it in its normal position. Nor will it cure the prolapse. But they may and do often provoke serious irritation of the kidney by the pressure they exert which will eventually lead to inflammation in or about the organ.

2030 Broadway.

DISCUSSION.

Dr. Carl Wagner, Chicago—In every operation on so delicate an organ as the kidney cryoscopic examination is a most important preliminary step. This most scientific means of diagnosis of disease of the kidney has been greatly perfected and used extensively with great advantage and satisfaction by the eminent workers, Von Koranyi, Leopold Casper, Friedrich Richter, Kummel, Beckman and others. It is in use all over Europe, while we hear little of it in America as yet. By the author's new suture, which places the kidney in an absolutely physiologic position, is secured a more perfect result than we have ever achieved before. I have used a similar method[1] on the stumps of ablated uteri. I called the suture a guy-rope, and it is intended to hold the stump in position against the parietal wall of the peritoneum. It is fastened over a Maydl bridge and keeps the stump of the uterus in that position until the external wound is closed. The guy-rope is a silk suture carried through the stump and knotted at its end, so that it can easily be removed when the granulating wound is almost healed shut. I have done the same thing on the kidney by putting two lateral sutures through the capsule and fastening over a Maydl's bridge, left *in situ* for twelve days with great satisfaction. The strip of gauze which Dr. Goelet inserts under the lower pole of the kidney for drainage corresponds to some extent to Dr. Senn's method, with the only difference that the gauze strip is used by the latter in larger size and serves as a rest and means of suspension for the lower part of the kidney. I would leave this strip in about six days, so that it not only drains but also favors the development of granulations, as another reliable means for fixation of this organ.

Dr. L. H. Dunning, Indianapolis—I believe we have not yet found the ideal method of operating on the kidney, although 159 successes ought to commend any method. Dr. Goelet's success, however, I think, is due quite as much to the gauze as to the method of placing the stitches. I long ago gave up the idea of attempting to retain the kidney with stitches without opening the fibrous capsule, which, if allowed to remain intact, serves as an obstacle to the formation of firm adhesions unless you get them from the perinephritic fat. I believe that if Dr. Goelet would leave out his gauze and use only his method of suturing he would have an occasional failure. I can not see the advantage of leaving the fibrous capsule intact. I have never observed any ill effects from opening it; I have opened it at least 40 times. The objection that he advanced, that the kidney has been anchored too low by former methods, is true. If the kidney is anchored as indicated in the drawing, through a vertical incision, even this method will leave the kidney lower than normal. We often find that we can palpate only the lower pole of the kidney even when we incise close to the twelfth rib. We must pull the kidney down into the wound. The kidney is about two-thirds of an inch above the twelfth rib in many cases, if not in the average case, so that even in these cases we anchor it lower than normal. But I do not believe that that cuts any figure whatever in the results. I do believe that the opening of the capsule is very beneficial in overcoming the attendant pain and in helping to establish stronger adhesions to the contiguous parts. The after-treatment is very essential. Constipation and vomiting being among the most frequent causes of poor success in the anchoring of the kidney, I look very carefully after the bowels. I do not give any food that is likely to cause fermentation, and whenever there is a tendency toward, or a desire for, a bowel movement the patient should be assisted in every possible way. This is so important that it is advisable for the operator to look after it himself.

Dr. Edwin Ricketts, Cincinnati—A record of 159 operations in three years with no failures is the best record in this country or Europe. I want to commend the silkworm gut suggested, and also the practice of bringing the kidney higher up without splitting the capsule; and yet, possibly, there might be one thing to take into consideration, and that is, if in the future that kidney might be affected with Bright's disease, such a splitting of the capsule, if that is a cure of Bright's disease, could have prevented the occurrence of that disease. I agree with Dr. Dunning that without the use of the gauze Dr. Goelet would have had some failures. The gauze must of necessity bring the kidney higher up than any other operation that has been devised. I do not think that it is wise to slit the capsule, because this is a healthy kidney and the slitting opens the door for infection. The operation is to be commended from that standpoint and also because of its simplicity.

Dr. John G. Clark, Philadelphia—What constitutes a movable kidney? In every abdominal section during the last two years where the incision was of sufficient size, I have introduced my hand, passed it backwards into the loin and, with the patient in the Trendelenburg posture, letting the tips of the fingers lightly rest on the ventral aspect of the kidney, gently drawn it downward to its lowest possible point. During this maneuver an assistant measures the distance traversed by the arm to estimate the range of the kidney. I am certain that too little stress has been laid on the fact that under normal conditions the right kidney may be a very movable organ. I have always looked with considerable scepticism on a simple movable kidney as a factor in the exaggerated symptoms which are sometimes attributed to it. If the mobility is slight and the symptoms are markedly of the gastro-intestinal type, a general enteroptosis is usually the principal factor. In the measurements of the range of mobility of the right kidney I have found that it was seldom under 2 cm., and many times from 3 to 4 cm., and yet the history of the case showed no symptom whatever that could be ascribed to this apparently undue excursus of the kidney. The left kidney seldom has a mobility of more than 2 cm. With these definite anatomic facts before us, it would be well to study a case very closely before we determine that a kidney, the lower pole of which may be distinctly felt below the borders of the floating rib, is a distinct pathologic entity. We are frequently told that movable kidneys are not relieved by abdominal binders. This, I believe, is in a large measure true, but in many instances of so-called movable kidneys, where binders or properly fitted corsets are applied, the patient experiences a considerable if not total relief. This is an apparent paradox, but apparent only, for such cases come under the classification of enteroptosis rather than of true movable kidney. I believe that the classical symptoms of marked gastric indigestion more or less dull or acute pain on the right side, marked respiratory mobility of the kidney, which may be so exaggerated under bimanual palpation as to force the kidney well down toward the pelvic brim or Dietel's crises, must be looked on as coming directly from the undue range of mobility, and that such cases may be considered as favorable for symptomatic relief in the event of a successful suspension or fixation of the kidney. In my opinion there are but three methods of fixation which should be considered: 1. By suture, very much as Dr. Goelet has described. 2. By splitting the capsule, turning it back and using it as a suspensory medium. 3. The use of a rubber tube or gauze as a sling to lightly

1. Chicago Med. Recorder and Jour. of Obstet.

draw the kidney up into the wound and hold it there until adhesion has taken place sufficient to retain it in an unmovable position. For more than a year I employed the stitch suggested by Brödel from his anatomic studies, which is similar to that described in Dr. Goelet's paper. The principle of this suture is that by its triangular introduction it snares, as it were, the connective tissue stroma of the kidney and thus bears more strain than does the simple suture passed directly into the cortex of this organ. I do not believe this suture can be improved on. The only question is the serious one, is it advisable to introduce directly into the pulp of the kidney any suture? I know well that, as a rule, no serious complication follows this procedure, but I believe it would be better and more rational to employ the method suggested by Edebohls. For the last year I have constantly employed the latter, and am so far entirely satisfied, although I have not had sufficient experience to justify me in fully commending this method. The third method has not appealed to me as a satisfactory surgical procedure, although Beyea, Penrose and others have had success with this method. Until I have further evidence my choice of method will be that described by Edebohls.

DR. C. S. BACON, Chicago—Does Dr. Goelet use the subcuticular suture and also drainage?

DR. GOELET—I use the subcuticular suture for closing the skin only.

DR. C. L. BONIFIELD, Cincinnati—Many movable kidneys do not really require an operation. A movable kidney is somewhat like a hernia. The vast majority of hernias in the adult require operation, but I have known cases of inguinal and femoral hernia to disappear when the patient became robust and took on additional flesh, and to recur during or after a long spell of illness. I think the amount of mobility of a kidney depends largely on the amount of perirenal fat. Many of the cases operated on for movable kidney do not require surgical treatment at all, although I do not mean to question Dr. Goelet's cases. I would advise the general practitioner to treat the neurasthenia, the indigestion and the general health of the patient.

DR. D. H. CRAIG, Boston—I have seen a number of cases of movable kidney associated with splanchnoptosis that have suffered materially through the perfectly honest and conscientious efforts of general practitioners who, in trying hard to keep abreast of the times, have prescribed abdominal belts. The belt supports temporarily and possibly benefits the patient for the time being, but only in a certain degree. After the belt has served this purpose the patient is left in a worse condition for operative procedure than before.

DR. A. H. GOELET, New York—One reason why this suture is as strong as it is, and why it will pull the kidney up into its normal position under the rib without tearing out, is that no matter which way you pull on it the traction is in an upward direction parallel to the surface of the kidney and its fibrous capsule and not at a right angle to it. There is one objection to leaving the drain in for more than twenty-four hours. I find that when I remove the drain there is a great deal of accumulated discharge behind it, and if this discharge is allowed to remain there it will get in between the kidney and the structures of the back to which the kidney has been attached and thus interfere with the formation of adhesions. That is, the gauze ceases to be a drain after that time. I laid particular stress on the importance of stripping the colon from the kidney. I believe that is one of the most important points in making a success of the operation, and one of the most frequent causes of failure when it is neglected. Where it is left attached to the kidney, if it does not pull the kidney loose it will drag on it and cause pain and other disagreeable symptoms. I have left the gauze drain out in a number of cases and have had success in every instance. Sometimes I think it is not necessary. When there is very little fatty capsule to get out of the way I frequently leave out the gauze drain and my results have been just as good. As to stripping the fibrous capsule from the kidney, I see no reason for mutilating the kidney in this manner when we can secure fixation just as well and better without doing so. If the detached fibrous capsule is utilized for fixing the kidney it is invariably fixed too low down. I have had a number of patients come to me after operation by that method by other operators, and they were still suffering, though the kidney was fixed, even worse than before the operation. I therefore oppose that method of securing fixation of the kidney. I see no reason for considering this a serious operation, as Dr. Clark contends it is. If I can do 159 nephropexies without a death—and others may have the same results if they adopt the same method—it can not be a very serious operation. My sutures do not penetrate the parenchyma. The needle may wound it in penetrating beneath the fibrous capsule, but that is insignificant and does no harm. Formerly, when a patient would not consent to an operation I yielded and ordered a belt. But now I never prescribe a belt before operation if I can avoid it. In the first place it delays the operation because the patient gets temporary relief, but she invariably comes back worse than before, and the operation becomes a necessity sooner or later. Two years ago I was consulted by a lady with a prolapsed kidney that was causing symptoms. She felt obliged to postpone operation and I prescribed a belt. She returned a little latter saying that she felt so well that she would not have an operation done. Two years afterward she came back to me for another trouble. I asked her to let me examine the kidney, which she said was giving her no inconvenience. I found it fixed in an abnormal position as the result of perinephritic inflammation caused by irritation from the belt, and examination of the urine showed a pyelonephritis, which did not exist at the time of her first visit. This is an illustration of what the belt will do, and emphasizes the necessity of early operation to correct the malposition. The corset, or any other form of external support, is to be placed in the same category with belts and is open to the same objection.

INHIBITED TUBAL PERISTALSIS: A CAUSE OF ECTOPIC GESTATION.*

O. G. PFAFF, M.D.
INDIANAPOLIS.

In submitting this contribution for your consideration, its brevity may be urged as a virtue. A great deal has been written concerning the etiology of ectopic gestation, some of which has approached demonstration, more has been speculative, but certainly much has been done toward the solution of many of the attending phenomena.

The function of the ciliated epithelium of the oviducts has been made much of as the chief, if not the sole, motive force in the transportation of the ovum into the uterine cavity. Building on this assumption Tait and others have attempted to show that in the destruction of the cilia by the inflammatory diseases of the oviducts, the function of the tubes is destroyed and the resulting inertia is to be regarded as the prime factor in the production of tubal pregnancy.

According to Lilienthal, Williams and others, the most frequent site of the chorionic attachment is at the isthmus, near the uterine horn, which would make it appear that if the cilia are really the essential factors of the transportation apparatus the destructive force of the inflammation must have spent itself uniformly in the uterine end of the tube, which is not in accordance with the observed facts in the history of salpingitis. There are many instances of tubal pregnancy in which the cilia appear to be present in normal condition and abundance. In some cases anatomic peculiarities, such as sacculation

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

and diverticula, have been demonstrated and are apparently the determining cause of the abnormal location of the embryo. Aside from these purely mechanical and obstructive causes there are other pathologic conditions of the tubes resulting from inflammation which are entirely overlooked by the followers of Tait, and which are of a quality to be justly accredited as being direct causative agents in the production of extrauterine pregnancy.

Again, it is well known that a great many cases occur in tubes giving no history of disease and in which no local pathology can be demonstrated, so that the conclusion is that ectopic pregnancies occur in some instances in perfectly healthy tubes. From these considerations which might be presented in a more elaborate manner, I think we may justly question the accepted position of the ciliary motion as the force which paddles the ovum down the tubal canal into the uterine cavity, and that we are compelled to seek some other explanation of the performance of this function.

The fallopian tube is in a certain sense an excretory canal and is similar in its anatomy to the ureter, the vermiform appendix, gall ducts and the intestine. Like them, it is provided with longitudinal and circular muscles. In all of these organs we have long since assigned an important rôle to these ingeniously arranged muscular fibers. The intestine, the appendix, the gall duct and the ureter are known to engage in an active peristalsis when sufficiently stimulated by the presence of materials within the canal, which it is their function to excrete. There is apparently every reason to suppose that the similar function of the oviducts is performed in identically the same manner, although the peristalsis of the tube when admitted at all has been referred to as a very minor and insignificant attribute.

I believe that for the performance of their function, that is, the physiologic emptying of all mucomuscular tubes, Nature has provided a general method, viz., peristalsis. This action when not interfered with by pathologic conditions or untoward influences operating through the nervous system, is at all times efficient and does not depend on an auxiliary force for the successful performance of its function. That ciliated epithelium does not invariably possess the function of a propelling force is evident by its presence in the lateral ventricles of the brain. There is a ciliary wave toward the body outlet in all mucous surfaces which have this peculiar epithelium, but it seems to be for defensive purposes.

In the fallopian tube I believe the cilia are provided for another essential and an entirely different purpose. The ovum is a most perishable structure, one whose delicate walls could not withstand the pressure of contracting mucous surfaces brought into apposition through the agency of peristaltic force. Therefore, in order that this force may not prove fatal to the ovum, it is necessary that some provision be made by which it shall be protected from this peristaltic pressure in its journey to the uterine cavity. Now, the arrangement of the cilia provides a bed of velvet on the pile of which the hope of the race safely rests in passage. The pressure of the visitor through the delicate ciliary bed conveys the signal to the presiding nerve center and the rhythmical muscular contractions are at once inaugurated and the ovum is gently rolled along into the uterine cavity. If we admit that peristalsis does play a very important part in the transportation of the ovum, then certainly the numerous factors which occasionally operate to produce paralysis of function in similar structures may fairly be regarded as causes of tubal gestation.

We are familiar with the serious results of inflammatory adhesions affecting the intestines and the appendix, not only in the mechanical constrictions, but also the interference with peristalsis from the abnormal fixation, and it is extremely probable that similar affections of the tubes are equally potent to work disastrous interference of function. The reflexes must not be ignored in this consideration. When an impacted calculus in the urethra causes such evidence of bowel obstruction that operation is determined on, it is not unreasonable to suppose that the function of the tubes may be likewise affected in a similar manner and degree.

Psychical effects are also of noteworthy importance. We are familiar with the cases in which the menstrual function has been immediately and permanently abolished through the mysterious influence of some profound and sudden revulsion of feeling, some horrible experience or great shock, etc. The hope or fear of pregnancy not infrequently generates the subjective symptoms and many of the physical signs of that condition. Evidence is not lacking to sustain the belief that similar agencies produce in the tubes results of a like quality to those observed in similar structures which offer more abundant opportunities for demonstration.

A very suggestive case, recently referred to me by Dr. Patten of Morristown, Ind., is worthy of notice:

Mrs. B., aged 32, the mother of one child, 4 years of age; no history of pelvic disease could be ascertained; during her pregnancy no unusual symptoms had been noted other than some slight intestinal disturbances; since her confinement, however, she had experienced rather frequent attacks of a colicky pain in the umbilical region.

Feb. 19, 1903, I was called to operate on her for a painful, elongated tumor of the left lower abdomen. Her last menstruation had occurred one month previously in a normal manner. The only symptom complained of was the rather sharp and persistent pain in the left side. A laparotomy proved the tumor to be the pregnant left fallopian tube distended to the size of a sausage roll and firmly attached at the fimbriated extremity to the transverse colon. The uterus was apparently suspended in this manner, the fundus inclined toward the right side, the left horn occupying the highest point near the median line.

I can see but one explanation of this peculiar malposition of the tube. It could not possibly have been the result of the ordinary chance occurrences, but was undoubtedly carried upward with the development of the pregnant uterus (possibly a pregnant left horn) becoming firmly adherent to the colon through the agency of an unrecognized inflammation, and, as the uterus receded following delivery, this rare relationship was maintained. The attachment to the gut was of a very firm and intimate character, requiring the most careful dissection in its separation. As a result of this firm attachment the tube was constantly stretched between two practically fixed points, the weight of the uterus continually taking up whatever slack the colon was disposed to grant. Under these circumstances there could scarcely be any possibility of tubal peristalsis, and when pregnancy occurred within the inert tube there was no force present capable of propelling the ovum down into the uterine cavity, and the chorionic attachment near the fimbriated extremity of the tube was the result.

As the tubes both appeared to be anatomically normal, it seems to me that the logical conclusion is that the abnormal location of the gestation sac was due to the inhibition of tubal peristalsis. I will also suggest that the inflammatory thickening of tube walls, and also the splint-like action of adhesions, may so interfere with

peristalsis that tubal pregnancy may result, regardless of the condition of the cilia.

There is undoubtedly a lack of positive knowledge concerning the pathology of ectopic gestation, and this presentation of an unusual phase of the subject is made with the hope that it may in some slight degree stimulate further investigation relative to this important matter.

DISCUSSION.

DR. L. H. DUNNING, Indianapolis—We can not dismiss the subject on the ground that we know nothing about it, for the reason that we know that there are conditions which are at least conducive to the development of an ectopic gestation, such as crippled and diseased tubes, malposition, loss of cilia and thickening of the tube by endometrial deposits, etc. Dr. Pfaff is very logical, but I do not believe he has settled the question.

DR. HUGO EHRENFEST, St. Louis—The theory advanced by the essayist is very interesting and very similar to the hypothesis advanced some time ago by Oliver, an English gynecologist. He also contends that the lack of peristalsis in the tube has much to do with an abnormal lodgement of the ovum in the tube. He suggests a connection between absence of sexual feeling and lack of peristalsis in the tube. During the sexual orgasm the uterus and, in all probability, the tubes contrast. Oliver believes that in women who lack sexual feeling entirely there may be a lack of peristalsis in the tubes. I think, however, that a paper published about a year ago by Opitz solves the question of the etiology of ectopic pregnancy satisfactorily. Almost all the investigators made the place of implantation of the ovum the object of microscopic examination. Opitz limited his investigations to that part of the tube lying between the site of implantation and the uterus itself. He examined 23 pregnant tubes, cutting the desired portion of the tube into serial sections, and in every one he found changes due to inflammatory processes. Of course, the changes were different in degree, but he found common to almost all the tubes a thickening of the mucous membrane, a partial destruction of the epithelium, and that very many of the adjoining folds were agglutinated at their edges forming blind hollows or sacs. That would give us a very plausible idea for the occurrence of tubal pregnancy. There are cases on record where the abnormal implantation of the ovum was explained by the fact that there was a congenital diverticulum of the lumen of the tube. Such a malformation of the tube, however, is very rare. If the formation of such blind alleys really is an almost typical result of inflammatory processes in the tubes, as suggested by Opitz, it would seem natural that ova should often be caught in these sacs on their way from the ovary to the uterus.

DR. G. BETTON MASSEY, Philadelphia—Several years ago, by inquiry in a number of these cases, I learned that a large proportion of women suffering from ectopic pregnancy had some time previously been subjected to forcible dilatation of the cervix. I do not mean to say that the dilatation caused the subsequent extrauterine pregnancy, although it might have done so. But a more probable explanation is that the dilatation was done for a condition which did not prevent the consequence of that condition. The dysmenorrhea being really due to a mucopurulent catarrh the dilatation was not a success. This subject of forcible dilatation as a cause of extrauterine pregnancy deserves further investigation. Abnormalities of pelvic functions should be considered more as a physiologic deviation, and not as though the pelvic organs were a non-vital mechanism which could be patched up every time the mechanism was out of order.

DR. J. H. CARSTENS, Detroit—In nearly all cases of ectopic gestation one of Nature's methods is to cause adhesion of the tube somewhere to prevent a so-called tubal abortion; thus the fetus is held in the tube and hemorrhage prevented, and if the tube distends it does not cause the passage of the fetus and the placenta out of the end of the tube, but in the direction of least resistance, that is, in the broad ligament. With hemorrhage in the broad ligament there is less danger. That generally subsides on account of the dense peritoneum covering which is one of Nature's methods of preventing death. We find adhesions in every case, but nearly all are recent. The tube is adherent to the rectum, sides of the pelvis or bladder or anywhere, showing that there has been an old adhesion; some old lesion that has not been absorbed and has probably caused a twisting of the tube, preventing its physiologic action and thus inducing the ectopic gestation. This contribution adds one point to the complex and diversified etiologic factors that produce extrauterine pregnancy.

DR. F. F. LAWRENCE, Columbus, Ohio—Interstitial extrauterine pregnancies occur in the uterine portion of the tube, and also in the fimbriæ ovarica. What effect can peristalsis have on these parts? Again, nearly all have noticed, in operations for salpingitis, constricting bands all along the tube at irregular points which practically occlude the tube, so as to prevent the passage of spermatozoa or the unfructified ovum. Several of these bands frequently occur on a tube that otherwise has no evidence of serious inflammation. Are not these partial or almost complete bands an exciting factor? Has any one had a case of ectopic gestation in which there was not found on close questioning a history of tubal trouble prior to the pregnancy? I have yet to find a case in which there was not a distinct history of tubal trouble, especially premenstrual pain or irregular menstruation. Every woman who is or has been the subject of tubal inflammation, no matter of what variety, is in danger of tubal pregnancy.

DR. C. O. THIENHAUS, Milwaukee—I believe there are many causes for this malformation. The idea has been advanced that all cases of extrauterine pregnancy show previous gonorrheic infection of the appendages. It is true that careful examination of many cases will reveal that a previous inflammation existed in the lower abdomen. In other cases we find that the patient has one child and after a period of three to five years, during which she showed at one time symptoms of tubal inflammation, she becomes pregnant in the tube. But there are other cases. I found in one case a cyst in the broad ligament as large as a man's fist, the tube on the right side was hanging over the cyst containing on its fimbriated end, which was adherent in the depth of Douglas' pouch, the extrauterine gestation. In another case I found a dermoid cyst of the ovary as large as a man's fist, which was probably the cause of the extrauterine pregnancy. The appendix in this case was found in a state of chronic inflammation and adherent to the gestation sac. Diverticula in the tube may be another cause. It is essential not to forget that in all cases of tubal pregnancy that part of the mucous membrane of the tube on which the ovulum is implanted must have been normal at the time of nidation.

DR. A. PALMER DUDLEY, New York—Many women become pregnant who have appendages very much adherent. It is not a question of imperfection of the tube. In my judgment the cilia play a larger rôle than has been accredited to them. But we must not lose sight of the fact that the dynamics of the abdominal cavity enter in here in the matter of the conduction of the ovum into the uterine cavity, as will be better illustrated by the records of cases where a hydrosalpinx is drained through the uterus. The constant diaphragmatic action of the pelvic floor; the action of the diaphragm and intestines plays an important rôle in the passage of the ovum from the ovary to the uterus. The most important question, I think, is the patency of the tube, no matter whether the lining is ciliated or not; it is a vent. As an illustration that the tube may be occluded and pregnancy take place is a case recorded by Bandl, where a vaginal hysterectomy was made and the uterine extremity of the tubes brought down into the vaginal vault. This woman became impregnated and had a tubal pregnancy of two and a half months, which aborted into the vagina. In my judgment the question of patency of the tubes is the all-important one, and then the dynamics that assist in carrying the ovum to the uterus.

DR. T. J. BEATTIE, Kansas City—I believe that every case of ectopic pregnancy would show a history of preceding trouble in the tube in some portion of the pelvis. About a

year ago, in a ruptured tubal pregnancy, I found a small cyst in the broad ligament.

Dr. O. G. Pfaff, Indianapolis—As we all seem to think, there is in most of these cases a pre-existing tubal disease, but I have found pregnancies in tubes that were absolutely normal, although this is probably rare. In reply to Dr. Lawrence, the uterine end of the tube is just the point where we get most of our tubal pregnancies. The object of the paper was to get away from the purely mechanic causes of tubal gestation and to consider whether there is not some explanation to be found in the interruption of tubal peristalsis.

CONSERVATIVE SURGERY OF THE SCLEROTIC OVARY.*

HUGO O. PANTZER, M.D.
INDIANAPOLIS.

The real risk to life appertaining to the early peritoneal surgery, in the past, incurred and justified very radical measures. The comparative safety of the modern methods of operating no longer sanction special indications and rules for this field of surgery. Utmost conservatism is the essential characteristic of the principles and practices of general surgery. To-day these must apply to, and, fortunately, quite generally prevail in, gynecic surgery. Efforts along this line show eminent successes, albeit many disappointments as yet attend such a course. Its limitations require as yet greater definition. The notable gratifying result obtained in the following case has offset, in the writer's experience, many less satisfactory and even disappointing results from conservative operative work persisted in through many years. Its narration here, it is hoped, may have it exert its stimulating effect on the efforts of those likewise engaged.

Cirrhotic ovaries at this time, I believe, are quite generally accepted to afford the indication for their immediate removal. My experience is not ample enough to draw deductions from. The case about to be recited pertains to cirrhosis without decrease in size of the ovaries. Pertaining to sclerotic ovaries with shrinkage of the organs, the writer has no case of resection that was followed by pregnancy. However, it seems warranted from the subjective relief afforded in some instances and from the unmistakable evidences in some cases of an attempt on the part of Nature to restore the already lost function, that even in the shrunken ovary the morbid process can be arrested by timely conservative surgical effort. The writer hopes soon to report his experiences with such efforts.

The extensive and exhaustive consideration of this subject on this occasion by our worthy president relieves the writer from entering into a detailed consideration of the mooted points in connection with the following case:

History.—Mrs. C. L. F., Kidley, Ill., aged 25. Married four years, desirous of having offspring, no conception. First menstruation at 13. Menstruation irregular, commonly retarded, is always painful before and during flow. Following a heavy lift at 18 patient suffered constantly with pain in left inguinal region. At periods she bloats, and has sacral, pelvic, occipital and frontal pain. Poor appetite, depression and growing emaciation, weakness and suffering mark her complaints. She has occasional transient attacks of bladder irritability and suffers from constipation.

Status præsens.—Patient is a small, lean, weakly woman. Floating tenth ribs, both kidneys movable. Thin, relaxed abdominal walls, flat miserable thorax. Uterus in retroflexion, somewhat fixed by contracted left broad ligament. Left ovary imprisoned by adhesions, tender, enlarged. Right ovary normal size. Slight contraction of internal os uteri.

Diagnosis.—Retroflexed uterus. Prolapsed and enlarged adherent left ovary.

Operation.—Deaconness Hospital, Jan. 16, 1902. Internal os was dilated. No curettage. Median celiotomy. Tube and ovary on left side were massed by inflammatory adhesions. No pus was found. Left ovary had cyst the size of filbert at one pole. Both ovaries were densely and thickly sclerotic, rather larger than normal size. Left ovary was removed entirely. A narrow wedge was cut from the entire length of the convex border of the right ovary. This displayed a ledge of sclerotic tissue one-eighth of an inch and more in thickness, revealing no evidence of normal ovarian stroma in this area. The ovary in its deeper parts, like in the superficial parts, bled very slightly, but in contrast with the latter revealed small islets of what seemed normal stroma. Indeed, this was so little apparent as to, in my estimate, include very little promise. However, there had been menstrual flow which could not be discountenanced. The surface of the ovary was pared in wedge form, the base of the wedge being at the border. The central slit was sewed with interrupted catgut sutures. It was striking that there was practically no bleeding. The uterus was ventrosuspended by its anterior surface near the fundus.

Patient made an uneventful surgical recovery, though her strength was slow to grow. Her feebleness preceding her operation seemed accentuated at this time.

Results.—Patient reported for examination two months later. There was some general improvement all along the line, though general conditions were still very unsatisfactory. Menstruation had occurred regularly, with lessened local and reflex suffering. Hygiene, iron, ergotin, strychnia and aloes were prescribed.

Patient reported again July 17, 1902. There was great general improvement, physical and psychical. She walked like an entirely different woman. She had missed her flow and was anxious about this. She complains of some pain through the sacral and lumbar region. Bladder had continued occasionally irritable, more so latterly.

Examination.—Uterus is found in good position, enlarged, softened, not tender. Vaginal mucosa softened and edematous, of bluish color. Right ovary to touch feels quite normal as to consistency, though obviously small. There are no evidences of ovarian adhesions.

Diagnosis.—Pregnancy.

March 17, 1903, patient writes me of her happy confinement with a fine nine-pound boy two weeks previously, and expresses her and her husband's unbounded happiness over the event.

DISCUSSION.

Dr. L. H. Dunning, Indianapolis—Dr. Pantzer's innovation worked well in this case. But he himself raises the question whether this method is commendable, viz., to leave such a large raw surface on the ovary. I have always felt it safer to cover all raw surfaces of the ovary. I think Dr. Pantzer's experience was unique in that he had no hemorrhage. I have never been able to do so much cutting on the ovary as he did without experiencing considerable difficulty in arresting hemorrhage.

Dr. A. Palmer Dudley, New York—I do not question that Dr. Pantzer left the ovary an open wound. He said he closed the wound by a circular suture. If he did that there was no necessity of covering it with peritoneum to get good results. Cirrhosis of the ovary is due to obstruction of the circulation. His case was complicated by adhesions and dislocations, and one ovary contained a cyst. I have operated on very many of these cases and have seldom found a true cirrhotic ovary fruitful after any form of treatment. I think the relief the ovary obtains from this method of treatment was not due solely to the ovary itself, but to the repair of pathologic conditions that accompanied the cirrhosis and the ovary also

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

derives benefit from the development of a new circulation. It is wise not to cut the ovary crosswise. I never operate on an ovary to save any portion by incising it crosswise, as we in that way section the nerve supply of the ovary and do material injury. If it is necessary to remove portions of the ovary it should be done along the upper horizontal surface of the ovary; one can take out almost any quantity of tissue and still have the remaining portion act because the ova are on the outer surface of the ovary although some follicles are found as low as the hilum. Unless operated on in the manner described by Dr. Pantzer the circulation is renewed through different channels, the uterus is restored to its position, and the ovary after a time receives new life. The thickened tissue will undergo fatty degeneration and in that way the ovary is restored to a normal condition. I am so situated in the Harlem Hospital that I can do anything I please without question. During the past winter I have been experimenting on tuberculosis of the testicle. I find that I can split the testicle in half and unite the wound with fine silk suture, sweep out the tubercular deposit, touch it with formalin and carbolic acid, and have a distinct recovery without rise of temperature. So the work described by Dr. Pantzer is only another evidence of how much work can be done on the uterine appendages of women.

DR. H. O. PANTZER—The method of operating in this case is open to the objection that raw surfaces were left involving the possibility of intestinal adhesions. This risk is unavoidable here. A close search subsequently for evidence of adhesions in this case failed to detect any. Perhaps the risk from a raw surface is magnified in our minds. In days past when adhesions were frequent, non-absorbable sutures were generally used, and undoubtedly often were the cause of adhesions. Permanent adhesions giving trouble nowadays are certainly rare. In the class of cases to which this belongs the family interest at stake is great and seems to warrant taking an unusual risk. In the light of the result obtained in the case reported the procedure may be justified. I have done conservative work on the ovary many years. Nine of my cases were followed by one or more pregnancies. I have attempted conservatism where sclerosis is associated with shrinkage of the ovary, so far with no more result than to produce the evidence of menstrual molimen in cases which had been without this and without any flow for months, and even several years. This result would seem to indicate the possibility of obtaining definite results if operation is early undertaken. Waldeyer confines the area in which ova are found to a small rim one-eighth of an inch in thickness adjacent to the greater part of the outer surface of the ovary. This does not tally with microscopic evidence often found where the internal tissues about the hilus disclose ova. Clinically I have had the opposite evidence in two cases, where all but the parts of the ovaries about the hilus were removed and yet pregnancy followed.

AN OLD-TIME QUACK EYE DOCTOR,

THE CHEVALIER JOHN TAYLOR.

BROWN PUSEY, M.D.
CHICAGO.

Indexed under the heading "Charlatans," in the magnificent library of ophthalmologic literature of Dr. Casey Wood, there is to be found "The Life and Etraordinary History of the Chevalier, John Taylor, Ophthalmiator, Pontificial, Imperial and Royal; in two volumes; written from authentic materials and published by his son, John Taylor, Oculist; London, 1761." In looking this book over, I happened on Chapter V of the second volume, which is an oration said to have been delivered in the streets of Oxford. I quote this chapter extensively, and when one has read it, I think no apology from me will be necessary for calling attention to it; and when one realizes that this oration is said to have been delivered in the public streets, and after Taylor had sent "his harbingers before him" to deliver his hand bills, I believe the desire is natural to inquire as to what manner of man this ancient quack was.

"The Eye," says the Chevalier Taylor, "that most amazing, that stupendous, that comprehending, that incomprehensible, that miraculous Organ, the Eye, is the Proteus of the Passions, the Herald of the Mind, the Interpreter of the Heart, and the Window of the Soul. The Eye has Dominion over all Things. The World was made for the Eye and the Eye for the World.

"*Let there be Light*, that first Fiat of the Almighty, and there was Light. For whose Use, I pray? For the Use of Man, for the Use of the Eye. The Angels wanted it not. The Sun was kindled, the Stars were lighted up; the grey Dawn and the Milky way, the Constellations, the Morning Planets, and all the bright Chandeliers over Head, were all hung out, rank and file, to minister to this little Speck, this Peep-hole of the Mind, this Inlet of the Soul, this Surveyor of the Universe, this Lord of all Things, the Eye.

"The Eye is the Husband of the Soul; through it she conceives, becomes pregnant, and brings forth Knowledge.

"Amazing how such large Objects find a Passage through so small an Aperture.

"The Eye is indefatigable. The Eye is an angelic Faculty. The Eye, in this Respect, is a Female. The Eye is never tired of feeling; that is, of taking in, assimilating, and enjoying all Nature's Vigor.

"All Nature is but one great Act of Love. The material and immaterial World conceive and bring forth together. The other Senses are the Soul's Gallants, such as Hearing, Feeling, Smelling, and so forth, with which she intrigues a Moment or two, and then returns to her lawful Husband, the Eye.

"The Children got between the Soul and the Eye, are legitimate Nature's genuine Issue; some of which can only with herself expire; the Brats of the other Senses die as soon as born.

"In corporal Generation too, how powerful is the Eye! It is the Signal of the Affections; and with a single Glance can proclaim the Pulsations of the Heart. It is the Lightning of Desire, and the Loadstone of the Soul; whose magic Effluviums inchant the Imagination, attract the Coalitions, irritate the Muscles, stimulate the Nerves, and brace up the whole Apparatus of Propagation.

"The green Mantle of the Earth, the azure Night-gown of the Sky studded so thick with Gold, the Trees, the Flowers, and the Gardens, the Gems, the Carbuncles, and even the Diamonds themselves, begot by Nature in the secret Womb of the Earth, are all brought forth by the Midwife Industry, are all polished to the purest Ray, to entertain, to regale the Ravished Eye.

"We owe the Ladies to the Eye, those Transcripts of the Angels, those Specimens of future Bliss, those Fountains of Joy, those Dainties of Desire, those Cordials of all human Care, who people the Earth with their Energy, and the Sky with Inhabitants; these Patterns of Purity and Love, these Master Pieces, these lucky Hits of Heaven, are the finest Regale for the Eye of Man, where it feasts on the Ruby of the Lips, the Vermillion of the Cheek, the Snow of the Forehead, and the Cherub in the Eye; and yet even these are but the Signs, the Invitations held out of that extatic, that soul absorbing—But Language is too weak.

"This is the greatest Good the Eye can give us. Without the Eye what were all this amazing World of Charms? a mere Mouthful of Moon-shine, a Sheet of blank Paper, a Candle in the Desert; for my Lady is no more than Joan in the dark.

"What an Orator is the Eye! that Short-Hand, that Cypher of the Soul, whose single Glance conveys a Volume.

"The Tongue is an Upstart, a tedious Intruder, a limited Prate-roast; who speaks the Language of a single Kingdom or County perhaps, and that but poorly too. Words are an artificial, tedious, contracted, obscure and imperfect Commerce, a Kind of *Hocus Pocus*, a juggling Compact, agreed upon by a few and understood by fewer still; a Messenger sent a round-about Way to the Understanding through a certain, dirty, winding Canal; where a little Wax can stop its Career, or a paltry Fiber unbraced, destroy the whole Business.

"As far as the bungling Productions of human hands are inferior to the exquisite Works of Nature, so far is the Faculty of the Eye above that of the Tongue. How many Ages old was the Creation before that Babel, that Jargon of Sounds called Language, was sent among Men as a Curse?

"The Eye is the Orator of Nature, and talks the Language of the Universe, of all beneath the Moon, of all above it: It talks the Language of Heaven too; it renders useless all Sounds except the tender Moanings of Lovers, those turtle Cooings of Desire, those nameless Throbbings of Fruition; these, these are the genuine Dictates of the broken Raptures

of the Soul, which she scorns to shape into Words; nor can she lose Time in so base a Labor.

"The Eye is the quick Flash, the instant Lightning of the Piece. Language is the Shot that loiters after with much Noise, indeed, but seldom hits the Mark.

"O ye Sons and Daughters of Minerva, ye Children of Wisdom, ye Offspring of Oxford, how precious is the Eye! . . Of what importance is its Office? How deserving is the Art that keeps its Springs in Order, and preserves the Interchange of Office betwixt the Works of Nature and the Soul! Mind and Matter are kept in constant Traffic by the Eye.

"The three mortal Foes to Sight (my learned Sons of Wisdom) are the Glaucoma, the Cataract, and the Gutta Serena; with these I wage eternal War. These Auxiliaries of ancient Night, that would restore her gloomy Reign, and bring back Chaos to the World once more.

"My Art, O ye Sons of Oxford, my Art is the Ally of Heaven itself, and aids even the Almighty, obeying still, and still performing the omnipotent Behest, *Let there be Light.*"

Fortunately, it is possible to learn something of the Chevalier Taylor and his family—a family which becomes more interesting when it is known that the Chevalier's father, as well as his son and two grandsons, were physicians. Indeed, the son and two grandsons, probably influenced by the worldly success of the Chevalier, followed in his footsteps and waged war against the "Auxiliaries of ancient Night."

Our authentic information of the Taylors comes from the writings of the Chevalier and his grandson, John Taylor, the third. We have from the pen of the Chevalier, "The History of the Travels and Adventures of the Chevalier John Taylor," London, 1761, and from the grandson, "Records of My Life," by John Taylor, Esquire, in two volumes, London, 1832.

Mentally the Taylor stock evidently was good stock. The sire of our oculists was a man of ability, and was a surgeon of prominence in Norwich, England. We are told by one of his colleagues that he was highly respected in his private as well as in his professional character. In the light of the history of the son, the Chevalier, a statement of one of the senior Taylor's friends becomes interesting. This statement was to the effect that the old gentleman had so grave and dignified an aspect and demeanor that the superstitious among his neighbors imputed supernatural knowledge to him, and on any disasters or losses consulted him as a conjuror. It is a well-recognized fact that the latent energy in a lie is enormous, and here we have the intimation that the same is the case in other forms of imposition. Maybe the tricks of the sire as a conjuror was the beginning of the quackish proclivities that later were so highly developed in his descendent.

The Chevalier Taylor was born in Norwich, England. In his own memoirs he does not give the date of his birth, nor does he say much of his early life; in another history of him we are told that he was born in 1703. He does, however, suggest the idea that the place of his birth may one day be judged worthy of the notice of posterity. Of his birth and early days the comments to be found in another place are interesting. One finds the statement: "He no sooner began to distinguish objects than he expressed the greatest aversion to all spots, either on the garments or countenances of those to whom he came near. Patches worn on the face being then in fashion, he often scratched them off and sometimes brought the blood along with them; nay, even then he put some eyes in danger!" Certain it is that in the birth of this man there was the beginning of the life of one of the master quacks.

The methods now in vogue among quack eye doctors seem to be used by all of them. In their advertisements they speak of "new system," "cross-eyes cured without the knife," "dissolvement treatment," or "absorption method," "optic nerve diseases." They advertise that they have written books on "Eye Diseases Cured Without Surgery," "Cross-Eyes," "Cataracts." "Eye Tests," etc. These books are usually described as a "Brief Treatise on the Application of His Remarkable Discoveries." In their advertising pamphlets—their "books"—they tell of their extensive travels and of the great opportunities they have had for the study of the conditions they want to treat; they publish the names of people whom they claim to have cured of awful complaints (particularly names of people in public positions, e. g., a United States Senator), and they publish pictures of conditions which they claim to have cured (these pictures frequently are taken from some standard work, but, of course, are claimed as original). The great standby of the modern quack, as we all know, is the "new system of curing cataract by absorption" and "cross-eyes without the knife."

Our great quack's methods were the same as those in vogue now. He had the new system of curing cross-eyes and cataracts, he published books describing his great opportunities, and giving the names of his patrons and giving pictures of the conditions that he cured. But his was a master's hand. In comparison the quacks of the present day are a cheap lot and they are not to be mentioned in the same class with this old faker.

Taylor's advertisement on settling in England after he became an old man is the book we before spoke of, "The History of the Travels and Adventures of the Chevalier John Taylor, Ophthalmiator, Pontificial, Imperial and Royal." Even the binding of these books—the history is published in three volumes—shows the superiority of his methods over those of the present-day quacks. The volumes are bound in handsome leather with gilt edges. The modern quack puts out his books with paper bindings and his picture on the back. (By the way, these pictures usually show a bald-headed, elderly man, with whiskers and a general expression which may be taken as indicating kindliness and knowledge and offer a terrible proof of that truism that appearances may be deceptive.)

The modern quack's pamphlet opens with interviews taken from the daily papers. Not so the Chevalier's history. The three volumes are dedicated respectively to his son, to David Garrick, and to the Merchants of London. The very first paragraph of his preface is interesting and shows his shrewdness. "Notwithstanding, by the title of this work my readers are prepared to be chiefly acquainted with numberless extraordinary adventures of my life, I flatter myself that it will not be displeasing if I here observe that I have not forgot the object most worthy of my attention, I mean the profession in which I have so long labored to be distinguished." The key-note of his book is found here; the book is for the purpose of impressing the reader with the author's professional greatness, while he is led to believe that it is a record of travel and adventure. The second volume of the history at my command has an interesting bit of evidence of the Chevalier's success in this particular in the book plate of some collector, which may be taken as indicating that the volumes at some time were considered worthy of such a mark. No bibliophile of the present would so mark the book of a modern quack.

It would not be profitable to follow far the adventures of the Chevalier. According to his statement he traveled through England, Ireland and Scotland from 1727 to March, 1734; from that time to November, 1735, he was in Paris and the towns of France, then to England for a few months, but back to Paris in 1736 and 1737; during 1738 and 1739 he spent the time in Spain; then to Lisbon and the towns of Portugal until 1742; then to England, Ireland and Scotland, where he remained until February, 1747; then to Germany during 1748, '49, '50, '51; then to Sweden, Russia and Germany until 1755, when in January he went to Italy, where he remained until January, 1757; then to Austria, Germany and Holland; then in January, 1759, to Scotland and through the towns of that country and Ireland and back to London in 1761, where, according to his book, he was ready for business.

In the journey, of course, he had experiences worthy of relating, but with few exceptions his stories are unentertaining and tiresome. In these travels he learned the various languages, and he calls attention to the necessity for one like himself to know the languages of the different peoples.

As was said, it was evidently his method of advertising to publish books written in the different languages of the various countries that he visited, and his travels may be traced by these books. In his list of books written by himself he claims to have published forty-five. One of his favorite titles is "Mechanism of the Eye," which he published in English in 1727, in French in 1737, and in Spanish in 1738.

The year 1743 found him again in England, where he published a "Dissertation on a very Extraordinary Case Under the Care of the Chevalier Taylor." Among his publications was "An Accurate Description of 243 Different Diseases to Which the Eye and Eyelids are Exposed," which first appeared in 1747. He announces this same title in his list of publications as a new book in High Dutch, in 1751, and again the same title in 1771. A copy of this work fortunately is in the possession of Dr. Wood. One of the striking features about it is the handsome binding—just as we would expect from the "Chevalier." The drawings are crude and, at least from our point of view, are worthless, but certainly even now would attract the attention of the untrained observer. We have in the particular volume at my command a singular bit of testimony bearing out this latter suggestion. This volume, in which, by the way, the text is in both German and Latin, in its career has been in the hands of a layman—as was no doubt according to the original plans of the author—who presented it to a relation, an ophthalmologist, with the letter from which the following is copied:

"If it has intrinsic value, so much the better; if not, keep it lying around where your patients can see it. It looks so learned you can without hesitation charge them in two languages."

It has been intimated that Taylor was a successful quack in a worldly way. If his book may be believed he was very successful. Good evidence of this is shown in the letters warrant from the potentates of the countries that he visited. These letters are published as foot notes in the first volume of his "History"—evidently so placed that he who runs may read. The first one of these letters published is from Pope Benedict XIV, who appointed Taylor Ophthalmiator Pontificial. He was appointed oculist to George II, King of England, and he received similar appointments from Augustus III, King of Poland, Frederick V, King of Denmark and Norway, Adolphus Frederick, King of Sweden, and many other lesser lights. In the list of famous people whom he treated are princes and princesses, dukes and duchesses. He announces that in the thirty years of travel he had treated over 80,000 patients. He speaks of one of his important cases in the person of a man who seems nearer to us than the princes and dukes and the like—of Handel, of whom he says: "I once thought to have had the same success, having all circumstances in his favor, motions of the pupil, light, etc., but on drawing the curtain we found the bottom defective."

It is hardly necessary for us to call attention to the fact that the Chevalier was a knave. This is abundantly shown in all of his career. In a few places he is honest enough to point this fact out clearly, as, for example, where he relates the story of his preparing to marry a dying old woman for her money, and how the plan failed when the fact was exposed that he already had a wife.

The Chevalier, always thrifty, pursued one plan when he finally located in England, which the modern quacks do not use, and which appears to have advantages. This plan is brought out in a notice to the reader in the back of the third volume of his "History." He calls attention to the great suffering of the poor in England from eye diseases, and he suggests to the prosperous of the nation that each subscribe two guineas yearly, and that all who do this are entitled to send during the whole year the poor thus afflicted to the Chevalier's son's house in Hatton Garden, where the Chevalier himself will gladly assist.

And now we come to the winter of this charlatan's discontent. The old man evidently planned to finish his days in London, where he proposed practicing with his son, who had become an oculist and a successful one, as is indicated by the fact that he was oculist to the king. Probably the old man had become fond of his grandchildren, as we hear of him playing in particularly high spirits with John Taylor, third, when he was an infant. But his plans miscarried, and he did not die at home at last. Rather a note in the autobiography of his grandson—the one who became oculist to George III—tells us that he died abroad.

And we have to relate that his grandson, in his "Records of My Life," deals this master quack a great blow, for he says that the "Life and Extraordinary History of the Chevalier John Taylor" was not written by his son, but was really written by Mr. Henry Jones, a literary hack of the olden days, partly from the recollection of notes once in the possession of the Chevalier's son, but "almost wholly of his own invention." In this case, the great oration at Oxford was probably not made at all by the "Chevalier," and taking this honor away, little is left of him except of unsavory memory.

New Instrument.

A NEW AND SIMPLE DEMONSTRATION OPHTHALMOSCOPE.*

GEORGE F. SUKER, M.D.
CHICAGO.

This little device which I have constructed, and which is to be attached to the indirect ophthalmoscope as made by the

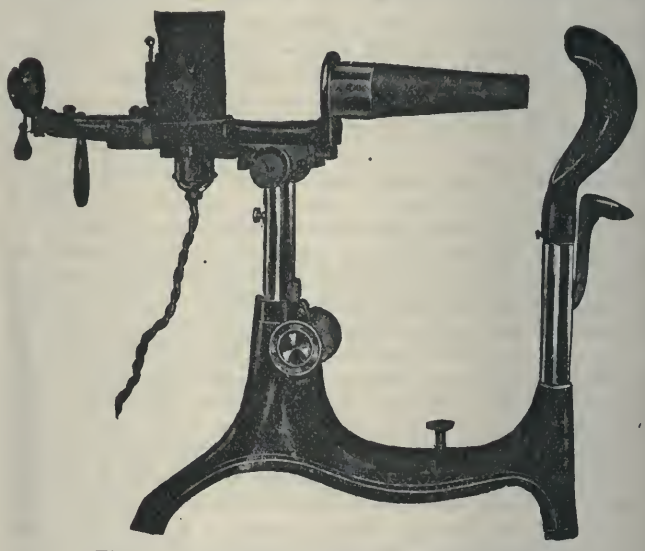

Fig. 1.—The original Geneva ophthalmoscope.

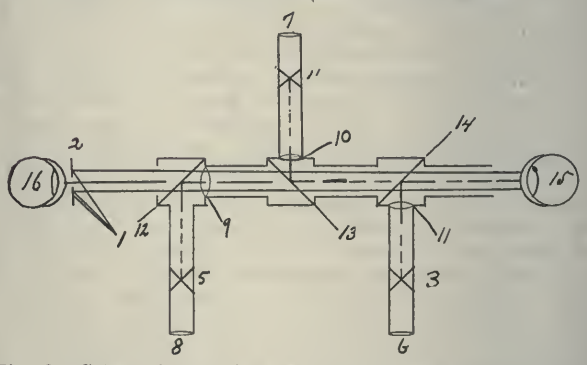

Fig. 2.—Schematic drawing of tubes. 1. Source of light. 2. Mirror (tilting). 3, 4, 5. Indirect images of fundus. 6, 7, 8. Convex lenses to suit observer. 9, 10, 11. Convex lenses, stationary. 12, 13, 14. Plain lenses placed at an angle of 45 degrees to axis of tubes. This gives a reflection of 90 degrees. 15. Patient's eye. 16. Observer's eye.

Geneva Optical Company of Chicago (Fig. 1), is solely intended to simplify the teaching of ophthalmoscopy in the schools. With it, two or three students in addition to the demonstrator can see the same fundus at the same time. The patient's eye is under the direct control of the demonstrator at all times, in that it can follow the movements of the latter's finger.

The chief value of the instrument consists of these points: It is simple; a number of students are able to see the same

* Exhibited before the Section on Ophthalmology of the American Medical Association at the Fifty-fourth Annual Session.

fundus; it can be detached from the original instrument. This allows one to use the original ophthalmoscope without the demonstration attachment.

The accompanying cuts will clearly show the construction of the instrument. The drawing (Fig. 2) plainly shows how the light, which is reflected from the mirror, reaches the fundus

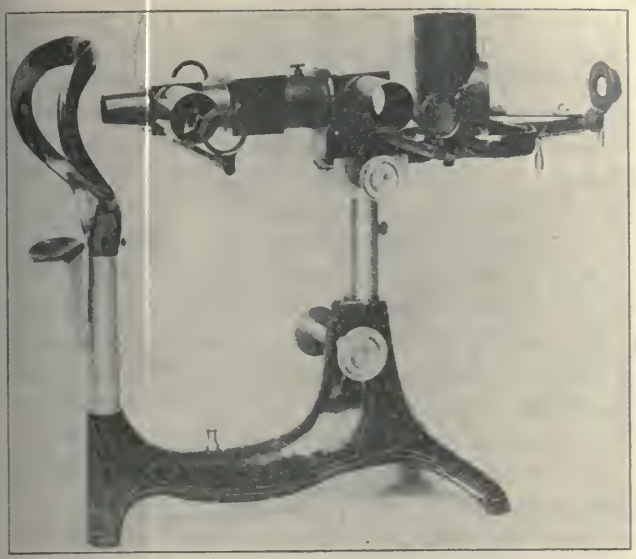

Fig. 3.—This shows the demonstration tubes in their proper position.

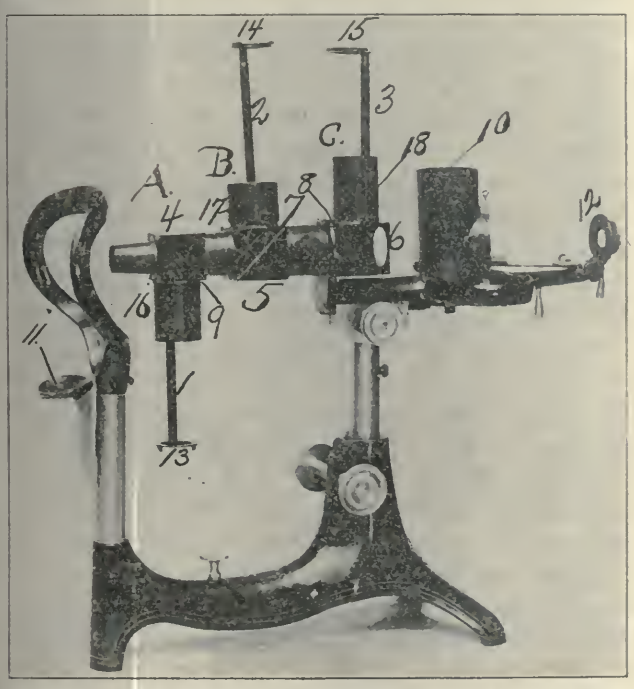

Fig. 4.—Photograph of the original model as shown at the meeting. It simply demonstrates the correctness of the principles involved in a demonstration ophthalmoscope. 1, 2, 3. Telescopic rods. 4, 5, 6. Small square boxes in which are placed slides at an angle of 45 degrees to the axis of the tubes. 7, 8, 9. Strong convex lenses at entrance of tubes. 10. Source of light. 11. Patient's chin rest. 12. Rotating mirror which reflects light into patient's eye. 13, 14, 15. Lens holders. 16, 17, 18. Tubes which open into boxes. A, B, C. The three separate attachments. C is inverted, as can be seen from the other illustration.

of the patient and how the student gets a view of this fundus.

The principles involved are those of indirect ophthalmoscopy and the total reflection of light from a highly polished and thin transparent media acting as a prism in a "camera obscura."

The loss of light intensity due to the numerous reflections is very trivial and does not detract from the clearness of the fundus picture. One gets a very large, as well as a magnified, field of the fundus at each position. There are no interfering corneal or light reflexes at any of the attachments. The examined eye must have a dilated iris, and the student must adjust the telescopic tube with a proper convex lens in the holder to suit his own eye. The instrument is best manipulated in the dark room. Either gas or electric light may be employed.

The instrument is a modification of the principles involved in the original Helmholtz's ophthalmoscope and clearly shows how simple it is to get a multiple image of the fundus.

The instrument which I show you is the original crude model. It is intended to show that the principles involved are correct and that a multiple demonstration ophthalmoscope can be made which is truly serviceable. It will be altered in minor details and more neatly constructed so that it can be more accurately adjusted. At the next session of the Section, I purpose to show a perfectly constructed instrument. This one is shown simply as a matter of record and priority.

103 State Street.

Clinical Report.

REPORT OF A CASE OF COMBINED DIAPHRAGMATIC OR "BIMANUAL MASSAGE OF THE HEART,"

DURING COLLAPSE FOLLOWING CHLOROFORM NARCOSIS.

H. M. COHEN, M.D.
VICTOR, COLO.

A woman, aged 32, perfectly healthy, with the exception of an adherent left ovarian cyst; no lesion of the heart, lungs or kidneys. The operation was for the relief of ovarian pain. The usual central, abdominal incision was made, with the patient in the Trendelenburg position. Chloroform was used because it is the choice of anesthetics at this altitude, 10,000 feet above sea level.

Fifteen minutes after the commencement of the operation the patient, without any previous respiratory, circulatory or pupillary danger signal, suddenly became cyanotic and pulseless, cessation of respiration in this case following and not preceding that of the heart. Artificial respiration was immediately resorted to and continued, and the usual hypodermics administered. After two minutes had elapsed and no reaction had been established, I introduced my left hand into the abdominal cavity, pushed along the anterior abdominal wall until the diaphragm was reached, and, placing the hand, palm upward, in about the position the heart would normally be; that organ was easily grasped through the relaxed and intervening diaphragm. There was an entire absence of heart action. Placing the right hand over the precordial region, externally, I now plainly palpated the heart, as it lay between my two hands. In other words, with the heart grasped between the two hands I was in the novel position for what I shall term "bimanual palpation of the heart." I then began rhythmical compression of the heart, using both hands, at a rate of about sixty times a minute. After about thirty seconds a slight beat was felt by the left hand.

The heart now began slowly to beat, gradually increasing both in strength and rapidity of beat, until at the end of one minute after massage began the beats registered about eighty per minute, and respiration began to be partially re-established. About two minutes after this respiration was normal, pulse eighty and, shock being apparently recovered from, the anesthetic was changed to ether, and the operation finished in about thirty minutes.

At the completion of the operation the patient was in good condition, there being no cyanosis or coldness of the extremities, pulse eighty-six and respiration about normal; consciousness returned in about the usual length of time.

Man's Enemies.—Humanity has but three great enemies, fever, famine, and war, of which by far the greatest, and by far the most terrible, is fever.—Osler.

MENDEL'S PRINCIPLES OF HEREDITY.

Although it is admitted that a clear understanding of the phenomena of heredity would be of great value in solving many of the perplexing problems of evolution, yet our knowledge of these phenomena has increased but little during the last century. The processes of fertilization and development have been studied in great detail, but we have as yet no idea as to what is the essential agent in the transmission of the parental characters to the offspring. Scientists have, however, begun to study the outward facts of this transmission, and we are gradually beginning to see at least how we ought to go to work at these problems. Among the workers who have contributed most toward the establishment of definite laws of heredity Galton stands perhaps foremost; but there is one other worker of equal prominence whose papers, however, remained unknown to scientists for 35 years after their publication. This investigator is Gregor Mendel, Abbot of Brünn, who carried on experiments in the garden of his cloister over a period of 8 years before any of his conclusions were put in print. His most important papers were published[1] in 1865 and in 1869, but nothing was known about them until 1900, when de Vries drew attention to them in a paper on experiments along similar lines. Mendel's very remarkable memoirs dealt with hybridization of peas, and he laid down in them what is now known as Mendel's principles, or laws, of heredity.

In cross-fertilizing peas having a distinct differentiating character he found that the hybrid character always resembles that of one of the parental forms so closely that the other either escapes observation completely or can not be detected with certainty. Crossing, for instance, peas having round seeds with a variety having angular seeds he got hybrids having only round seeds. Those characters which are transmitted to the offspring in the hybridization he termed the dominant, while those which became latent in the process he designated the recessive characters. The dominant character may come from either the seed-bearing parent, or from the one that furnished the pollen. In the first generation bred from the hybrids not only the dominant characters appear, but the recessive ones also appear with their full peculiarities, and this in the definitely expressed proportion of three to one. Among each four plants of this generation we have, therefore, three with the dominant characters and one with the recessive. No transitional forms were observed in any experiment. In the second generation bred from the hybrids those forms in which the recessive characters reappeared in the first generation remain constant. That is, all the offspring coming from forms having the recessive character in the first generation maintain this character in the second and subsequent generation. It is different, however, with those forms which possess the dominant character in the first generation bred from the hybrids. Of these plants two-thirds yield offspring which display the dominant and recessive characters in the proportion of 3 to 1, while only one-third remain with the dominant characters constant. Of 30 plants, for example, which came from round seeds of the first generation, 10 yielded round seeds (dominants), and 20 yielded round and angular seeds, in the proportion of 3 to 1. Both varieties may appear in the same pod.

It is seen from these experiments that the hybrids form seeds having one or the other of the two differentiating characters, and of these one-half develop again the hybrid form, while the other half yield plants which remain constant and receive the dominant or recessive characters, respectively, in the same proportion. There is no blending of the two differentiating characters. If new plants are used which differ in two essential characters instead of one, the results are still more complicated. The hybrid partakes of the dominant characters of each of the parental types, but if one of the latter possesses only dominant characters, then the hybrid is scarcely or not at all distinguishable from it. In crossing round yellow peas with angular green peas the offspring yields only round yellow seeds, because these are the dominant characters. The plants raised from these hybrids yielded seeds of four sorts, which frequently were found in one pod. Here again the recessive characters reappear in the first generation bred from the hybrids. Of these four sorts of seeds one variety, the angular green (recessive) remained constant in the second and subsequent generations. The others yielded both constant and hybrid forms, and this in a definite proportion of the individuals. The constant forms finally represent every possible combination of the associated characters, and hence the law may be stated briefly as follows: In the second and later generations of a hybrid, every possible combination of the parent characters occurs, and each combination appears in a definite proportion of the individuals.

The fact that constant forms appear in all combinations of the associated characters is very significant. Mendel found by experience that constant progeny is produced only when the egg cells and the fertilizing pollen are of like characters, so that both are provided with material for creating quite similar individuals, as in the case with the normal fertilization of pure species. But since the various constants are produced in one

1. Verh. d. Naturf. Ver. Brünn, 1865, Iv. See "Mendel's Principles of Heredity," by Bateson, for translation.

plant, or in one flower of a plant, he concludes that in the ovaries of the hybrids there are formed as many sorts of egg cells, and in the anthers as many sorts of pollen cells as there are possible constant combination forms, and that these egg cells and pollen cells agree in their internal composition with those of the separate forms. And he assumes further that the various kinds of egg and pollen cells are formed in the hybrids, on the average, in equal numbers. The last two statements are, of course, purely theoretical, but Mendel has produced very strong evidence in their favor by means of a complicated experiment in cross-fertilization.

The experiments outlined above have been confirmed with other plants, such as wheat and some species of beans, but contradictions are also encountered. It will now be interesting to see how far these laws are found true in hybridization of animals, a subject which we will consider in a future issue.

INTRACRANIAL TUMORS.

An interesting evidence of the encouragement scientific work in public institutions is receiving is afforded by the anatomic study of intracranial tumors by I. W. Blackburn,[1] pathologist to the Government Hospital for the Insane, Washington, D. C. In the profuse illustrations of this work there is a resemblance to certain famous old atlases of morbid anatomy which have long served as landmarks in medicine; a similar rôle undoubtedly awaits this contribution; it will be valuable for purposes of reference. The large number of black and white, unembellished drawings by Blackburn of microscopic preparations indicate an earnest zeal for this manner of recording observations worthy of hearty commendation. Seventeen of the tumors showed the structure of spindle-celled sarcomas and are designated as "endothelial." They arise from the dura as circumscribed, warty growths, compressing but not infiltrating the substance of the brain. Their slight attachment to the dura has frequently led to the erroneous supposition that their origin was within or from the cerebral tissue. Their location was more commonly the base of the brain, and the ease with which they could be "shelled out" from the surrounding tissues invites surgical intervention for accessible growths of this character with focal symptoms.

Some objections exist to classifying these tumors with sarcomas, and these are recognized in the rather naïve statement that they "can not be classed with any other division of morbid growths, consequently must be placed with the sarcomata or in a class by themselves." The absence of metastatic growths or regional extension, the thickened and hyaline blood vessels they contain and the disposition to undergo fibrous transformation and degenerative changes, especially calcification, are all in marked contrast to the characteristics of malignant tumors; they would denote instead the healing and cicatrizing inflammatory processes associated with large amounts of granulation tissue, or perhaps more closely ally these neoplasms to benign mesoblastic tumors. In two cases their origin from the endothelium of the arachnoid villi was demonstrated. It might not be out of place to suggest the name of "meningeal endotheliomа" for this class of growths. The tumor of this sort described by Brower and Wells[2] in 1901 was termed peri-endothelioma after the classification of endotheliomas by Borrmann. In addition to these tumors from the dura, 5 gliomas are described, a "gliosarcoma" and a small round-celled sarcoma. Of 3 tumors in the pituitary fossa, 2 arose from the hypophysis; the third, a cystic growth containing considerable cholesterin, was so altered by retrogressive processes that its origin could not be determined; the hypophysis, however, was not involved in the growth. In none of these cases were there any evidences of acromegaly. In view of the prevalent belief of a connection between this disease and tumors of the hypophysis, these 3 cases form a valuable addition to the few similar observations of growths from this structure without acromegaly. The structure of the tumors in the two cases of true pituitary adenoma does not differ materially from that usually described for tumors of the hypophysis; in one the proliferation had assumed a papillary character. The absence or presence of chromatophilic affinities of the cells in these growths was not determined.

It is possible to conclude from a review of this work that the equipment and facilities for research have not reached, in the Asylum for the Insane in Washington, a stage beyond that attained in some of our state institutions of a similar character. It would have added to the value of the report if the newer methods of technic had been employed in studying these intracranial tumors; their relation to the insanity and the secondary changes in the nervous system are phases connected with their examination on which we may hope to obtain information in the future.

There are scattered throughout this country hospitals for the insane with laboratories either under the charge of a single individual or with forces greatly overwhelmed by the wealth of material, whose efforts and enthusiasm are undirected and handicapped by traditions and financial policy. Notwithstanding these conditions, improvement is occurring slowly in the character of the work done, although greatly delayed by the necessity of educating "boards of control" and politicians to the humanitarian need of assisting scientific investigation in medicine. In some instances this improvement is denoted by lavish expenditures for apparatus and buildings with no provisions for the workers they were designed to accommodate.

The benefits of the thorough organization the profession is now undergoing will be apparent when, through the education of public sentiment, greater improvements

1. A Study of 29 Intracranial Tumors Found in 1,642 Autopsies in Cases of Mental Disease, 1903.

2. Am. Jour. Med. Sc., 1901, cxxii, 32.

are introduced into these laboratories and, through improved direction and co-ordination, more efficient use made of the opportunities they possess for research.

PARAGUAY TEA.

Some months ago a request was made in the *Journal of Tropical Medicine* that some reader in South America give information in regard to maté or Paraguay tea. In response to this it publishes in its October number a communication from a South American resident who points out certain special advantages of this as a stimulant.

It seems to be a fact that the ordinary South American or hybrid South American is not naturally an energetic individual, but under the influence of this physical and mental stimulant the amount of hard work that he can do is hardly limited. The woodmen in the quebracho industry go to the woods between 3 and 4 o'clock in the morning and work steadily for hours on an occasional swallow of maté, only stopping at their noon meal. The correspondent asserts that maté is far superior in its invigorating powers to tea, coffee or cocoa and that it fits one as well for mental as for physical work. It is prepared, as is tea, by pouring boiling water on the leaves, and it should be drunk immediately or sucked through a metal tube, the latter being the preferable way. The stimulating effect of three or four ounces will last for as many hours. The bitter taste is soon tolerated and even relished. The small amount of caffein as compared with tea or coffee is rather notable; less than one-half the amount in tea, and the lack of volatile oils which often disagree with digestion is another point in its favor. The correspondent thinks that from a hygienic point of view maté ought to be preferred to other beverages that contain caffein, as its stimulation is not at all debilitating. In only very rare instances has he ever seen it produce any untoward symptoms. Some very neurotic and neurasthenic individuals bear it badly and have their symptoms aggravated if they take it in excess. He admits that a maté habit may be acquired and may become persistent, though no very evil effects, he says, seem to follow. Taken cold, as is the habit with some of the laborers in South America, it seems to have a bad effect, but since they subsist almost entirely on it for days at a time it is not remarkable that they should be anemic and emaciated. They are, moreover, usually subjects of malaria, and it is claimed that taking cold maté in excess makes them more subject to the malarial infection.

There is some responsibility in suggesting a new stimulant to those who are already suffering from excess of such, but it may be that if Paraguay tea were introduced into this country it would help displace some more harmful drinks. The correspondent concludes his article with a quotation in which he says that "when the old world discovers its error in not utilizing the leaf of the ilex, and shall have found out that yerba maté is the cheapest, most wholesome and tone-giving of beverages, then the ports of Europe will be thrown open to the trade, and its population swell the demand for an article of diet that ranks among the very best." This opinion may be a little too favorable. We doubt whether maté will displace the daily beverage to which we are now accustomed, but it is nevertheless a possible addition to our luxuries.

CONSUMPTION NOT THE ONLY PROBLEM.

In its latest weekly bulletin the Chicago Health Department calls attention to the exaggerated statements that are sometimes made in regard to the prevalence of consumption, quoting one authority whose estimate would require 35 per cent. increase over the figures shown in the last U. S. Census reports, notwithstanding the fact that there has been a steady decrease all these years in the mortality from phthisis. This is only one instance of the exaggeration in which good men allow themselves occasionally to indulge when speaking of a subject in which they are strongly interested. Consumption is a scourge, but it does not follow that its evils should be overstated. A review of the consumption mortality in Chicago during the last half of the nineteenth century shows a decrease of over 40 per cent. in the ratio of mortality, at the same time that there is a 53 per cent. increase in the mortality from pneumonia since the beginning of the last decade of the nineteenth century. During the past few years the pneumonia mortality—though its excess is largely confined to about seven months of the year—has annually exceeded the total of deaths from consumption and there is a continued increased percentage of deaths from this cause. We can not credit the whole of this, as The Journal has long ago pointed out, to influenzal infection which has been rampant during the past ten or eleven years. We have other problems, therefore, beside that of consumption and which at present seem even more serious.

DANGER FROM SLEEPING CARS.

Apropos to the question of consumption we may refer to some statements made at the recent meeting of the American Public Health Association[1] in regard to the hygiene of railroad traveling, and especially of sleeping cars. One speaker said that the official investigation of a state board of health disclosed the fact that the blankets used in these conveyances were only cleaned once in every six months. Considering this in connection with the additional fact that was pointed out by another speaker that consumptives are constantly traveling on these cars, the matter becomes a serious one. There is no question that the chances for acquiring consumption are increased by modern luxuries of travel. The only consolation we have is that we have been taking these chances for many years without any appreciable harm, since consumption is apparently on the steady decrease, at least as regards its mortality, if not its incidence. This is no reason, however, for neglecting sanitary precautions, and we trust that railroad organizations, the Pullman Company and others that are re-

1. See Society Proceedings, page 1157.

sponsible for the present condition of things will bring about the changes that are needed to insure the safety of the traveling public.

POLITICAL CONTROL OF PUBLIC INSTITUTIONS.

We have troubles of our own, but there is sometimes, perhaps, a little disreputable satisfaction in knowing that others have them, too. The political management of public institutions in this country has become so patent an evil that we have almost reached the point where we accept it as inevitable. In some states the political patronage theory most seriously affects the usefulness of public charitable institutions and yet politicians can not be induced to give up what they consider their perquisites. This evil, however, exists elsewhere, and it is evidence of company in our misery to read in the *Intercolonial Medical Journal of Australasia* that the authorities there are practically the same in their methods and ideas as here. Our confrère says: "Whenever anyone attempts to overturn the belief that political patronage is the beneficial system of administration the commotion is sure to be active and immediate," and this is in reference to the stand taken by the chief secretary of the Colony of Victoria. Even in Great Britain influence may vitiate the choice of officers as in the case of one asylum a few years ago in the southern portion of the island. Nevertheless, we believe that we have been, and are, more afflicted with political control of charitable institutions than almost any other people—perhaps excepting some of the British colonies. The medical press and the medical profession have been too quiet about the matter, and it is time we used our influence as a profession to help bring the needed reform.

THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

This is one of the largest medical libraries in the world, and in many respects the best. The collection at the present time consists of about a quarter of a million medical books and pamphlets, of which 149,000 are bound volumes. One of the most important functions of the library is the preparation of its "Index Catalogue," of which one volume appears yearly. The first series of sixteen volumes, covering the entire alphabet, was completed in 1895, and the latest volume of the second series, recently published, completes all entries under the letter K. Although based on the Library of the Surgeon-General's Office, this unique work is practically an index of the medical literature of the world as published in book form and in journals. Both authors and subject-matter being indexed, it is available as a working catalogue in any large library, general or medical, and is so used in all civilized countries. This work is unique in the domain of medicine, of which it includes all branches, and in no other science or profession is the special literature indexed on the same large scale and in the same comprehensive way. The Index Catalogue is issued to public libraries and to important medical schools and societies. It is thus made as generally available to the medical profession of the country as the limited number of copies furnished will allow. Books are lent to individuals on the application of recognized libraries, assuming responsibility for their return, or if no library is available the loan is made subject to a money deposit to cover possible loss. In all cases express charges must be paid by the borrower. Rare volumes which could not be replaced in case of loss are not lent, but the great mass of literature in the library is thus put within the reach of the medical profession, to whom this excellent collection should be a source of legitimate national pride.

PRELIMINARY QUARANTINE.

Elsewhere in this issue is a communication from a correspondent containing a suggestion that, simple as it appears to be, seems worthy of attention. We all know the difficulties of diagnosis in the beginning of many infectious diseases. Diphtheria and scarlet fever are often hardly distinguishable from other conditions that are comparatively innocuous and that do not require any notification. The difficulty of diagnosing smallpox in its early stages is well known. Typhoid fever is often difficult to recognize in its incipiency. Nevertheless, it is not always possible to say when the danger of infection from these diseases begins, and the earliest warnings that can be given are advisable. The inconvenience, to say the least, of quarantining a house is such that it is advisable, where practicable, to be sure it is necessary before inflicting a home with a quarantine card. Our correspondent suggests, in cases in which there is a reasonable suspicion of a contagious disease, but in which the exact type is not yet ascertainable, that simply a notice of an infectious disease without any specification as to its nature be posted. While the idea is not a new one, having been carried out in some places, it is worth wider attention than it has received. We would amend our correspondent's suggestion by advising a card reading, "Quarantine, Probably Infectious Disease Here," to avoid the absolute declaration of infection until the diagnosis is sure. When the true nature of the disease is ascertained the attending physician could remove the card, and replace it with the one called for by the disease, or remove all quarantine if the disease proved to be non-infectious. Probably more hard feelings arise among physicians over the diagnosis of suspected cases of contagious and infectious diseases than over any other cause. If a preliminary quarantine notice would materially lessen this—and it seems that it would—here is one strong argument in favor of the measure. In some cities a card is used reading: "Quarantine"—in large letters—"Contagious Disease Here"—in smaller letters—thus suggesting that quarantine is the principal fact for notice and that it is not necessary to publish abroad details as to which particular type of contagion is represented. This would exclude the trespasser who boldly approaches a house labeled with a disease from which he has already suffered and of which he consequently has little fear, regardless of the danger of his example or of carrying the germs elsewhere. Such a card might be used for all quarantine and the exact diagnosis left to the attending physician. If a preliminary quarantine card is used, the public will be further educated on the important fact that certain diseases can not be distinguished in their incipiency.

Medical News.

ILLINOIS.

County Aids Sufferers.—The public service committee of the county board has set aside $2,000 to be used as an emergency fund for the relief of smallpox sufferers at Lemont.

Charged with Murder.—Two guards at the Illinois Hospital for the Incurable Insane, Bartonville, who are charged with having brutally beaten and abused an insane patient so that he died, have been held without bail to the grand jury, which convenes November 9.

Corrosive Sublimate for Calomel.—It is reported in the daily press that a baby in Mattoon recently died from poison. The mother took the child to the office of a physician, who, intending to give her calomel, gave her tablets of bichlorid of mercury. At the inquest the physician confessed his mistake and was exonerated by the jury.

Smallpox in Will and Cook Counties.—Dr. Elvin F. Baker, Jacksonville, inspector of the State Board of Health, after careful investigation, reports that there are 250 cases of smallpox in Dupage Township, Will County, and in Lemont Township, Cook County. The supervisors of both townships have agreed to establish a strict quarantine.

National Guard Medical Officers Meet.—The Illinois Association of Military Surgeons met, October 31, at Rush Medical College. The morning session was devoted to reports and papers; in the afternoon Professor Senn gave a clinic, and in the evening the members of the association were his guests at a dinner at the Chicago Athletic Club. Col. N. Senn, surgeon-general, was re-elected president; Major Thomas J. Sullivan, surgeon Seventh Infantry, vice-president, and Major Charles Adams, surgeon First Infantry, secretary-treasurer.

Chicago.

Personal.—Dr. and Mrs. Llewellys F. Barker sail, November 7, for Europe, on the *Lahn*.——Dr. and Mrs. Andrew M. Harvey are spending a few weeks in the south.

Increase in Infectious Diseases.—Diphtheria continues to increase—23 per cent. in the last fortnight—and scarlet fever fully 60 per cent. comparing the last half with the first half of the month. Three cases of smallpox were removed to the Isolation Hospital—all from Lemont and none vaccinated.

For New Laboratory Superintendent.—An original entrance examination will be held by the civil service commission, November 17, for superintendent of the city laboratory to succeed Dr. William K. Jaques, instead of filling the office from the eligible list of medical inspectors. Dr. Wynekoop will be in charge temporarily.

Mortality for the Week.—Of the total 473 deaths reported for last week, 63 were due to pneumonia, 52 to consumption, 48 to heart disease, 37 to Bright's disease, and 36 to violence. The death-rate for the week was at the rate of 13.07 per 1,000. This is higher than during either the previous week or the corresponding week of last year.

Dr. Frank Billings' Illness.—The many friends of Dr. Billings will be sorry to learn that it became necessary for him to submit to a second operation. He was doing well until a slight hemorrhage developed about 15 days after the operation, which finally became so severe that it was necessary to reopen the wound. Since the operation, which occurred October 31, there have been no more hemorrhages and the patient is doing well.

October's Deaths.—The total 1,962 deaths from all causes reported during October furnish an annual rate of 12.25 per 1,000. This is 13.6 per cent. less than the average October rate of the previous ten years, which was 14.19. With one exception it is the lowest October rate on record. There were 282 more deaths of males than females—an excess of 25 per cent. The 195 pneumonia deaths—almost 10 per cent. of the total—is unusual for October, and is ominous for the future, says the department of health.

Dr. Stevenson Critically Ill.—Dr. Sarah Hackett Stevenson, one of the most eminent medical women of America, and prominent not only in medical circles, but in all work for women, suffered a cerebral hemorrhage while in her office, October 30. She was taken to Augustana Hospital, and thence, on November 3, to St. Joseph's Hospital. She is completely paralyzed, and it is feared that the paralysis may be permanent. The Medical Woman's Club announces that the banquet which was to have been given in the honor of Dr. Stevenson, November 14, is indefinitely postponed.

INDIANA.

Infectious Diseases.—Typhoid fever is said to be raging at Goshen.——Lafayette has 18 cases of smallpox, all of mild type.——Dr. Seth B. Melton, Fontanet, reports 75 cases of smallpox in that town and its vicinity.

September Deaths.—The total number of deaths reported was 2,766, an annual rate of 13.4 per 1,000. In the corresponding month last year 2,812 deaths were reported, a rate of 13.6. In the preceding month there were 2,933 deaths, rate 13.7. By important ages the deaths were: Under 1 year, 519; from 1 to 5 years, 245; from 5 to 10 years, 65; from 10 to 15 years, 66; 65 years and over, 557. Some important causes of death were as follows: Tuberculosis, 347; typhoid fever, 166; diphtheria, 35; croup, 3; scarlet fever, 15; measles, 6; whooping cough, 5; pneumonia, 110; diarrheal diseases, 265; cerebrospinal meningitis, 35; influenza, 3; puerperal fever, 12; cancer, 92; violence, 184; smallpox, 2. The city death rate was 16.4 and the country death rate 11.8 per 1,000. The death rates of the cities having over 25,000 were: Indianapolis, 17; Evansville, 14.8; Fort Wayne, 14; South Bend, 17.2, and Terre Haute, 17.6 per 1,000.

Disease Prevalence in September.—Typhoid fever stood first in area of prevalence, as was also the case in the preceding month. Deaths occurred in 66 counties, there being a total of 166. Diarrhea was second in area of prevalence, as was also the case last month. Tonsillitis and bronchitis were more prevalent than they were in the preceding month. There were 68 cases and 2 deaths from smallpox in 16 counties. This is a decided drop as compared with the preceding month, also compared with the corresponding month last year. It is likely that all the cases were not reported, for it has appeared in the last few days in Clay County, among children, and was diagnosed as chicken-pox. The order of prevalence of diseases was as follows: Typhoid fever, diarrhea, tonsillitis, rheumatism, bronchitis, intermittent fever, dysentery, cholera morbus, scarlet fever, cholera infantum, pneumonia, inflammation of bowels, diphtheria, measles, pleuritis, influenza, erysipelas, whooping cough, puerperal fever, meningitis.

Personal.—Dr. and Mrs. Hamilton Wolfe, New Albany, recently celebrated the sixty-fourth anniversary of their marriage.——Dr. John Z. Powell, Logansport, has been placed in charge of the National Home for Disabled United States Volunteer Soldiers at Johnson City, Tenn.——Dr. Seymour C. Wilcox, New Albany, recently celebrated his eighty-fifth birthday.——Dr. Marshall Varble, Jeffersonville, has been operated on for appendicitis at Norton Infirmary, Louisville.——Dr. James W. Estes, Arlington, suffered a loss of $600 by a fire in which his instruments, office furniture and medicines were destroyed.——Dr. Walter R. Francis has resigned as treasurer of the Marion Hospital.——Dr. and Mrs. John M. Kitchen recently celebrated their golden wedding in Chicago.——Dr. Kent K. Wheelock, Fort Wayne, has sailed for Europe.——Drs. Ernest C. Reyer, Albert C. Kimberlin, and Thomas E. Courtney have been appointed members of the Indianapolis Board of Health.——Dr. Mavity J. Spencer, Indianapolis, has been appointed secretary of the board of health and city sanitarian.——Dr. Joseph D. Cain has been appointed superintendent of the city dispensary, Indianapolis.

IOWA.

Smallpox.—At Quincy 30 cases are reported, at Corning three cases have occurred, and at Runnells there have been 20 cases in the last month.

Personal.—Dr. John C. Rockafellow, Des Moines, has gone to Arizona on account of impaired health.——Drs. Hornibrook have constructed and opened a hospital at Cherokee.

Hospital Association Organized.—The Atlantic Hospital Association has been incorporated with a capital stock of $10,000 by Drs. Carlton V. Wilder, Thomas B. Morris, and others to operate a hospital in Atlantic.

Physician Enjoined from Practice.—In the case of Dr. Horace W. Barnard, Emmetsburg, who invoked the aid of the law to prevent Dr. J. C. Davies, whose practice, property and residence he had bought, from practicing again in Emmetsburg, the court has decided that the temporary injunction shall be made permanent, and that Dr. Davies shall not practice in Emmetsburg nor in Palo Alto County.

Lamoni Murder Decision Reversed.—The Supreme Court has reversed the decision of the lower court, by which Dr. J. W. Crofford, Lamoni, was sentenced to twenty years in the penitentiary for the murder of Miss Maude Stone by a criminal operation, on the ground that one of the jurors had expressed an opinion on the case and because of errors in the trial. Dr.

Crofford will accordingly have a new trial. Despite the refusal of the State Board of Medical Examiners to restore his certificate he has continued to practice since his release on bail.

KANSAS.

Typhoid Fever in Kansas City.—An epidemic of typhoid fever is prevailing in a small neighborhood in the central part of Kansas City, where 27 cases are reported.

Personal.—Dr. Claude Mayfield, Hutchinson, has been appointed health officer of Reno County, vice Dr. George R. Gage, resigned.——Dr. George M. Minney, Wichita, has been appointed captain and assistant surgeon, K. N. G., and assigned to Battery B.

Physician Found Not Guilty.—In the case of Dr. Jacob L. Hausman, Marysville, charged with having caused the death of Kate Strohm by a criminal operation, the state failed to produce any testimony against the accused, and the judge instructed the jury to find him not guilty.

License to Stay Revoked.—Dr. Robert E. Gray, Garden City, who was tried in Chicago for the murder of a girl whom he is said to have taken to that city to have a criminal operation performed, and whose license was revoked several months ago by the State Board of Medical Registration and Examination on the ground of his immoral character, has been refused a rehearing by the board.

MARYLAND.

Bequests.—Dr. William J. Todd, Mount Washington, receives $500 and Dr. Josiah S. Bowen $6,500, by the will of Mrs. Adeline P. Bowen.

Personal.—Dr. Alexander D. McConachie, Baltimore, has been elected professor of materia medica and therapeutics in the Maryland Medical College.

Hospital Society Election.—The first meeting of the Johns Hopkins Hospital Medical Society for 1903-4 was held October 12. Dr. Thomas B. Futcher was elected president and Dr. Charles P. Emerson, secretary.

Compromise Verdict.—The suit for $10,000 for alleged malpractice in an operation for tumor brought against Dr. Edwin B. Claybrook, Cumberland, was decided October 25, by a compromise verdict of one cent for the plaintiff. Dr. Claybrook is a B. & O. R. R. surgeon.

Deaths of the Week.—There were 184 deaths in Baltimore last week, an annual death rate for the colored of 30.43 per 1,000, and of the white of 13.12 per 1,000. There were 6 deaths from typhoid fever, and 20 each from consumption and pneumonia. Diphtheria is on the increase.

New Clinical Society.—The American Society of Clinical Surgery, a new national organization devoted purely to clinical demonstrations, will be organized at the Johns Hopkins Hospital, Baltimore, November 13. The committee in charge consists of Drs. Harvey Cushing, Joseph C. Bloodgood, and John M. T. Finney of the Johns Hopkins Medical School. The society will adjourn in the evening and go to Philadelphia, where several sessions will be held at the University of Pennsylvania and at the University of Pennsylvania hospitals. Dr. George E. Brewer, New York, is provisional president, and Dr. James G. Mumford, Boston, secretary. The aim of the society is to stimulate its members in original thought and research, to develop and improve methods of surgical teaching and to promote good fellowship among its members. A small membership and semi-annual meetings are proposed.

NEW YORK.

Personal.—Dr. Henry D. Didama, Syracuse, who underwent an operation October 25, is reported to be improving.

Cornerstone Laid.—The cornerstone of the new St. Luke's Hospital, Utica, was laid on October 17. Mr. and Mrs. Frederick T. Proctor, Utica, have given the site for the hospital and will build and equip it, and the whole will represent, when finished, an outlay of nearly $200,000.

Notice of Examinations.—The State Civil Service Commission will hold examinations for the positions of superintendent and resident physician in the New York State Hospital for the Treatment of Incipient Pulmonary Tuberculosis, Nov. 28, 1903, in various cities throughout the state. Intending competitors must fill out application blanks and file them in the office of the commission before noon of November 23. Applicants will be duly notified of the time and place of examination. Non-residents of the state will be admitted. The requirements and conditions of examination are as follows:

Medical Superintendent.—Probable salary, $3,500 a year, with quarters and maintenance for the superintendent and his family. The duties of the position are defined by Chapter 416 of the Laws of 1900, which further provides that such medical superintendent shall be a well-educated physician, a graduate of a legally chartered medical college, who has had at least six years' actual experience in the practice of medicine, including at least one year's experience in a general hospital.

Resident Physician.—Probable salary, from $900 to $1,500 a year, with quarters and maintenance. Duties to be prescribed by the medical superintendent, under the direction of the board of trustees. Candidates must be regularly graduated physicians and have had at least two years' experience in the practice of medicine, including one year's actual experience in a general hospital.

For full particulars, application blanks, etc., address Chief Examiner, State Civil Service Commission, Albany.

New York City.

Another Convalescent Hospital.—It is announced that a hospital for convalescents will soon be opened in connection with Lebanon Hospital.

Personal.—Dr. Louis Stern and wife were badly hurt by being pinned down by their automobile which was thrown into an unguarded excavation.

Resolutions on Dr. Pilgrim's Death.—The faculty of the New York School of Physical Therapeutics has adopted resolutions eulogistic of its departed associate, Dr. Maurice Fischer Pilgrim.

St. Luke's Hospital Report.—The managers of the hospital report that during the past year, ending with St. Luke's Day, there were treated in that hospital 2,642 persons, and that the expenditures exceeded the receipts by $32,166.81.

Lectures on Skin Diseases.—Dr. L. Duncan Bulkley will give a course of clinical lectures on diseases of the skin to the medical profession at the New York Skin and Cancer Hospital, on Wednesday afternoons at 4:15, commencing November 4.

Larceny of Hospital Supplies.—On complaint of the charities commissioner an attendant in the King's Park Insane Hospital, formerly employed in Bellevue Hospital, was arrested on the charge of having stolen from the hospitals of the department, bandages and other surgical supplies worth $4,000.

Druggist Not Responsible in Counter Prescribing.—The appellate division of the New York Supreme Court handed down October 30 an important decision regarding the legal liability of druggists for injuries received by patients whom they see fit to treat. The plaintiff alleged that he had received a slight cut on his thumb and that a drug clerk bandaged the wound and instructed him to keep the dressing wet with a carbolic lotion; that he had put five or six drops of the acid on the bandage, with the result that blood poisoning set in, necessitating the amputation of the thumb. The defense was that druggists were not permitted, under the law, to practice medicine or surgery, and that the plaintiff was guilty of contributory negligence. This contention was upheld both by the trial court and the appellate court.

OHIO.

Hospital Incorporated.—Mercy Hospital, Columbus, has been incorporated with a capital stock of $60,000.

Colored Hospital.—The Peter Fosset Memorial Hospital for colored people took corporate form October 8, when its board of trustees took formal charge. The hospital contains about twenty beds. Such a hospital has been much needed inasmuch as very few of the hospitals of Cincinnati accept colored people. The active staff is as follows: Drs. E. Duval Colley, Norval C. Vaughan, W. A. B. Kerr, Louis A. Cornish, and James C. Erwin.

Personal.—Dr. Benjamin F. Lyle, Cincinnati, has been made director of the bureau for the free examination of consumptives.——Dr. Herbert Bacon, Bloomville, has suddenly become totally blind.——Dr. Theodore W. Rankin, Columbus, has returned from abroad.——Dr. Carl Hiller has been appointed bacteriologist of the Cincinnati City Hospital, vice Dr. Albert B. Devers, resigned.——Dr. James Donnelly and family, Toledo, have returned from Europe.

New Sanitary Code Proposed.—A new sanitary code largely extending the powers of the Columbus Board of Health has been proposed by Dr. W. T. Howard, Jr. Under this code the board will be given enlarged power to control communicable diseases, the sanitary conditions of schools, factories, dwellings, offices, public buildings and vehicles, the protection of foods and the abatement of nuisances. Residences will be more strictly placarded and disinfected. District physicians will report on the cleanliness of school buildings. Teachers will be instructed in the symptoms of children's diseases. The New York rules have been adopted for controlling tuberculosis. The sale of rubber tubes for nursing bottles will be prohibited.

The Colleges.—The medical colleges of Cincinnati open this fall under slightly changed conditions. The medical department of the University of Cincinnati (Medical College of Ohio) opens with conditions unchanged except for additional equipment, and has registered about the same number of students as last year. The Miami Medical College has absorbed two minor colleges during the past year. One year ago the Cincinnati College of Medicine and Surgery closed its doors and a large part of the faculty went to Miami. During the past summer the Laura Memorial College, a woman's school, has been directly transferred to the Miami. The laboratories of the Laura Memorial College were well equipped and will be used by the Miami for teaching. The teaching privileges at the Presbyterian Hospital are transferred with the college. The attendance at the Miami will probably equal that of last year.

PENNSYLVANIA.

New School Book Committee.—As a committee for the examination of school text-books for the Pennsylvania State Medical Society the following have been appointed: Drs. Andrew B. Brumbaugh, Huntingdon; John W. Ellenberger, Harrisburg; Edgar M. Green, Easton; Edward Stieren, Pittsburg; and S. Solis-Cohen, Philadelphia.

The Allegheny Quarantine Matter.—The friction between the State Board of Health and the health officials of Allegheny in regard to dealing with the smallpox situation, has probably ended by the local authorities adopting the measures insisted on by the state board. There will likely be no general quarantine of the city, but quarantine will be vigorously carried out where found necessary, and reports of the condition will be made regularly to the state board.

Philadelphia.

Diphtheria is Prevalent.—There were 94 new cases of diphtheria for the week ended October 31 and 22 new cases of smallpox. Typhoid fever has materially decreased, there being 69 new cases for the week.

College and Hospital Personal Mention.—Dr. John H. Gibbon has been made one of the surgeons to the Pennsylvania Hospital to fill the vacancy made by the death of Dr. Thomas G. Morton.——Dr. Judson Daland, for 21 years a member of the faculty of the University of Pennsylvania, has been elected professor of clinical medicine of the Medico-Chirurgical College, to succeed Dr. William E. Hughes, resigned.

GENERAL.

The National Association for the Study of Epilepsy and the Care and Treatment of Epileptics held its third annual meeting at Philadelphia November 5.

Writers on hematologic topics, according to a letter we have received, are asked to send two reprints of their articles or two numbers of the corresponding journals to Charles E. Simon, M.D., American editor of the *Folia Hæmatologica*, 1302 Madison Avenue, Baltimore, for the purpose of review in that journal. In the place of reprints, authors' abstracts will also be received, and can be published immediately after, or coincidently with, the appearance of the original.

New Naval Titles Asked.—Surgeon-General P. M. Rixey, U. S. Navy, in his annual report calls attention to the lack of military rank in the titles now given the medical officers of the Navy and to the lack of dignity when the titles are compared with those of civil life or of other military services. He recommends titles which show both the rank and the grade, as follows:

> In place of surgeon general, surgeon admiral, and in the other grades, medical director to become surgeon captain; medical inspector, surgeon commander; surgeon, surgeon lieutenant commander; passed assistant surgeon, surgeon lieutenant, and assistant surgeon, surgeon lieutenant, junior grade.

Surgeon-General Rixey declares there is necessity for the thorough upbuilding of the Naval Medical School. He advocates the complete renovation of all naval hospitals in need of it. He recommends the building of a new hospital on Seavey's Island, Portsmouth, N. H., at least remodeling of the hospital at Chelsea, Mass.; and the enlargement of the hospital at Pensacola sufficiently to accommodate the sick of the fleets which maneuver in the Caribbean each winter. He asks that two hospital ships be authorized on plans evolved from the experience with the *Solace*, each to cost $1,630,000, and recommends a naval sanitarium for the cure of tuberculosis.

The Craig Colony Prize of $200 is offered by Dr. Frederick Peterson for the best original essay on the etiology, pathology and treatment of epilepsy. The conditions to be complied with are that the paper must show original research work; the subject-matter must be original; the paper must be accompanied by a sealed envelope containing the name and address of the author and bearing on the inside a motto or device, which is also to be inscribed on the essay; the manuscript must be in English and be sent to Dr. Peterson at 4 West 50th Street, New York, before Sept. 30, 1904. The successful manuscript becomes the exclusive property of the Craig Colony.

The Alvarenga Prize for 1903 has been awarded to Dr. William S. Carter, Galveston, Texas, for his essay entitled: "The Relation of the Parathyroids to the Thyroid Glands." Dr. Thomas R. Neilson, secretary, informs us that the College of Physicians of Philadelphia will make the next award of the Alvarenga Prize (being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about $180) on July 14, 1904. Essays may be on any subject in medicine, but can not have been published, and must be received by the secretary of the college by May 1, 1904. Each essay must be sent without signature, but marked with a motto and be accompanied by a sealed envelope having on its outside the motto and within the name and address of the author.

CANADA.

St. Boniface Hospital Addition.—A four-story addition to this hospital at Winnipeg, to cost $100,000, will be built.

Jubilee at Queen's University.—The medical faculty of Queen's University, Kingston, Ont., celebrated its jubilee, October 16, by the opening of a new physiologic and geologic building.

Tuberculosis Sanatorium for British Columbia.—The Ministerial Association of Vancouver desires a sanatorium in British Columbia, and a provincial association for the handling of tuberculosis will be formed.

Toronto Dispensary.—Last year about 13,000 of the sick poor of Toronto were here treated. The dispensary has quite outgrown the accommodation and equipment of the present building, and an appeal has been made for funds for the erection and equipment of a new building next spring.

Infectious Disease Circular in British Columbia.—The Health Department of British Columbia will distribute leaflets containing information on common infectious diseases among the school children. The object is to make the parents more familiar with these diseases. A daily report from the teachers regarding pupils absent through illness will be required whenever disease is prevalent or on the increase.

Personal.—Dr. J. C. Connell has been appointed dean of the medical faculty of Queen's University, Kingston, Ont., in succession to the late Dr. Fife Fowler.——Dr. William Bayard, St. John, N. B., has resigned from the chairmanship of the New Brunswick Board of Health. Dr. Bayard has for more than 40 years been active in board of health matters in that province, and is one of the oldest practitioners in Canada.——Dr. R. Tait McKenzie of the anatomy department of McGill University, Montreal, has been appointed chairman of the Canadian Committee for the St. Louis World's Fair Olympic Games.

A New Western Hospital for Montreal.—At the quarterly meeting of the board of governors of the Western Hospital, Montreal, held last week, it was stated that a new hospital would probably be erected in the spring and that it would provide good accommodation for at least 100 patients. The building would cost in the neighborhood of $100,000. The report of the medical secretary showed that 146 patients had been received into the ward during the past quarter while 1,941 consultations had been given in the outdoor department. The treasurer's report showed the finances to be in a satisfactory condition.

FOREIGN.

The Picture Postal Card in the Hospitals.—The Paris authorities have originated the idea of allowing each hospital to print a set of ten picture postal cards illustrating the various services and scenes in the hospitals. They are to be sold by the doorkeeper for the benefit of the sick.

Official Endorsement of the Biologic Blood Test.—Austria formally adopted, some time ago, this biologic method for forensic cases, and made arrangements for the production of the prepared serum for the purpose. Prussia has followed this example and recommends that this test should be used in forensic cases to supplement and complete others. Four stations have been appointed for the production of the serum and the carrying out of the tests, including the Institute of Hygiene at Greifswald, the Institute of Experimental Therapy at Frankfurt, and the Institute for Infectious Diseases at Berlin.

Some Statistics of Fatal Illnesses.—The physicians in Bavaria have been instituting an inquiry as to the number of persons without medical attendance in their last illness. They find that in a large part of the country a physician was summoned in less than half of the cases of illness that terminated fatally and in certain districts only 10.5 per cent. of the fatal cases had any medical attendance. The proportion is larger in the cities. In Baden 71.3 per cent. had had medical attendance and in Mosbach 62.1 per cent. Only 51.7 per cent. of the children under one year had had medical attendance during their last illness, but the proportion rises to 91.9 per cent. in cases of children more than a year old.

Novel Application of Drunkards as Object Lessons.—The cable states that the friends of temperance in the Russian city of Kieff have installed warm, comfortably-equipped halls in three different quarters of the town to which the police have orders to carry persons found intoxicated in the streets. Each hall is divided into two sections, one for men, the other for women. They are under the control of a physician, who sees that the "guests" are properly attended to until they become sober, when they are liberated. These halls are open to the public at all hours, the theory being that nobody but a confirmed drunkard will risk being seen by his townsmen lying drunk in a public hall. The halls have been in use a month and have sheltered intoxicated persons. The average time required for becoming sober was ten hours.

Vital Statistics in Germany.—The German government has recently published the statistics of the causes of death during the last twenty-five years in the empire. All diseases show a remarkably reduced death rate except certain gastro-intestinal affections. The general mortality has been reduced from 26.73 per 100,000 to 20.46. The average per five years of the deaths from tuberculosis has been reduced from 357.7 to 218.7; acute respiratory affections, from 308.6 to 258.5; typhoid and gastric fevers, from 43.6 to 10.4; diphtheria and croup, from 99.8 to 31.1; puerperal fever, from 14.4 to 5.1. On the other hand, the mortality of the acute intestinal affections, dysentery, etc., has increased from 264.1 to 287.8. The number of viable children born has also diminished. This higher mortality from gastro-intestinal affections is an actual retrogression, the report concludes, and attributes it to the increased participation of women in wage-earning occupations. The more women who enter industrial life the larger the number of infants who are deprived of breast milk. The above statistics apply only to towns of 15,000 inhabitants or over. Fuller details are quoted in the *Allg. Med. Ct.-Ztg.*, October 17.

A Warning to Wealthy Parents.—Under this heading reference was made last week to a sensational case of sadism in which the victims were the two sons of a wealthy Berlin banker entrusted to a private tutor. It seems that a Berlin neurologist had been briefly consulted by the mother, who commissioned him to go and visit her sons in the country to see if a course of suggestive treatment would be advisable to supplement the corporal punishment which the tutor applied in moderation with her consent to break them of long-established habits of masturbation and untruthfulness. He had asked for consultation with a specialist. The neurologist, therefore, visited them once and saw nothing suspicious—physical examination was not allowed by the tutor, who feared it might detract from his authority, and the neurologist had been particularly cautioned not to do or say anything to offend the highly prized and very sensitive tutor. The boys complained only of sleeplessness. The neurologist advised abandonment of corporal for psychic measures, and that a specialist should be sent down every month to inspect their progress. Even when the tutor was under observation for weeks in an asylum after his arrest, his appearance and behavior suggested nothing abnormal.

Battle of the Clubs in Germany.—The physicians connected with the medical aid insurance societies in Germany have resigned in a body at so many places that the advertisements warning outside physicians not to negotiate with the societies without consulting the undersigned, have become so numerous that they are now condensed into a single display ad in our German exchanges. Twenty-five towns are specified, and the name of the local representative of the *Leipziger Verband* is signed to each. The *Verband* announces that it will impart information at any time free of charge in regard to vacancies, medical assistants wanted and other matters of practical interest, with advice as to desirable points to locate in, etc. Our exchanges also comment with pleasure on the successful outcome of the negotiations between the medical officers and the societies at many points, thanks to the united stand taken by the profession. We note that the names of Gera and Mühlhausen are still advertised as points where the strike is still on, the particulars of which have been mentioned in these columns from time to time. The societies resort to numerous tricks to contract with outside physicians, the latest being to conceal both name and place in advertising, and have the mail addressed to the office of the advertising journal, sending a man to confer with the applicant at his home. Our exchanges no longer accept unsigned ads of this kind unless the writer is personally known to them.

LONDON LETTER.

The Sanitation of India.

An elaborate report on the sanitation of India in 1901 has been issued. The population amounted to 293 millions, showing an increase of 1.3 per cent. on 1891, but in several districts there was a considerable decrease. A marked relation was found between decreased population and diminished rainfall. The decennium included 2 famine years and cholera and plague were exceptionally prevalent. The decennial birth rates and death rates showed great variations; the highest provincial birth rate was 50.5, the lowest 14.67; the highest death rate was 119.9, the lowest 15.9. Cholera caused 4½ million deaths during the decennium. In 1901 the birth rate for the whole of India was 34.7, against 36.6 in 1900. The fever mortality was low, being 18.7 against 22.8 in 1900. The cholera death rate was low, 1.20, against 3.70 in 1900. The smallpox death rate was 0.40. It is estimated that about 33 per cent. of the children born are vaccinated. There was a large increase of plague mortality, the deaths amounting to 283,988, against 92,807 in 1900.

Correspondence.

Preliminary Quarantine.

ELMHURST, ILL., Oct. 26, 1903.

To the Editor:—I wish to suggest a plan that I believe, if carried out, would be of great value to the public and at the same time would relieve the physician of a great load of responsibility. It is difficult in the incipiency of many infectious diseases to establish a positive diagnosis. Measles, rötheln and scarlet fever are at times confused, as are tonsillitis and diphtheria, chicken-pox and smallpox. It is often difficult to establish a strict quarantine in these doubtful cases. The public, in general, has a wholesome dread of placarded houses, and the strict isolation of the patient would be fostered if in every infectious disease the house be placarded with a sign like the following: "Contagious disease here," or "Infectious disease here." This sign could be put up in the beginning of every infectious disease, and in this manner we could quarantine measles, rötheln, chicken-pox, parotitis and tonsillitis. This sign could be supplemented by the other placards of scarlet fever, diphtheria, etc., but this would not be necessary.

HENRY F. LANGHORST, M.D.

Marriages.

WESLEY G. BAILEY, M.D., to Mrs. Walter Elrod, both of Chicago.

ROY E. BROWN, M.D., to Miss Carolyn Hutt, both of Chicago, October 6.

EDWIN ELLIOTT ARMSTRONG, M.D., to Myrtle Demuth, both of Sylvania, Ohio, October 14.

CHARLES M. NODLER, M.D., to Miss Josephine Schnens, both of Denver, Colo., October 5.

JOHN J. MULDOON, M.D., to Miss Johanna Isabella, Dwyer, both of Chicago, October 19.

ARTHUR EMORY SUDLER, M.D., to Miss Louise Painter Gilpin, both of Baltimore, October 21.

EDWIN K. DINGES, M.D., Pekin, Ill., to Miss Margaret Alice Wood of Decatur, Ill., October 22.

FRANK W. LOCKWOOD, M.D., South Bend, Ind., to Miss Florence E. Jenkins of Tecumseh, Neb.

GEORGE H. VERNON, M.D., East St. Louis, Ill., to Miss Maud Cooper of Bradfordton, October 21.

CHARLES W. BURT, M.D., to Miss Jennie Margaret Barr, both of Valley Junction, Iowa, October 28.

FINN. KOREN, M.D., Appleton, Minn., to Miss Benedicta Solberg of Minneapolis, Minn., October 20.

EDWARD EUGENE GILLECK, M.D., to Miss Charlotte Irene Thompson, both of Niagara Falls, N. Y.

HERBERT POLLOCK CRAWFORD, M.D., Crafton, Pa., to Miss Florence Barr of Philadelphia, October 20.

CLAYTON C. PATCHEN, M.D., to Miss Arminta M. Reed, both of Mount Sterling, Ill., at Jacksonville, Ill., October 14.

RUPERT L. TURRELL, M.D., Conneaut, Ohio, to Miss Minnie Wheeler of Windsor, N. Y., at Cleveland, Ohio, October 20.

JAMES CLINTON BALLARD, M.D., U. S. P. H. and M.-H. S., to Miss Luda B. Bowman, both of Natchez, Miss., September 17.

LEE M. FRANCIS, M.D., Pueblo, Colo., to Miss Ethel Mary Waldron of Colorado Springs, Colo., in London, England, October 28.

Deaths.

John K. Lineaweaver, M.D. Jefferson Medical College, Philadelphia, 1861, a member of the American Medical Association, Medical Society of the State of Pennsylvania, and Lancaster County Medical Society, and president of the Columbia Board of Health for many years, died at his home in Columbia, October 18.

George C. Hays, M.D. Medical College of Indiana, Indianapolis, 1876, one of the founders of the Fountain County Medical Society, died at his home in Hillsboro, Ind., October 26, from tuberculosis, after a lingering illness, aged 67.

William R. McMahon, M.D. Rush Medical College, Chicago, 1868, chief surgeon of the Southern Railroad, Louisville Division, for several years, died at his home in Huntingburg, Ind., October 23, from apoplexy, aged 67.

Joseph N. Guerard, M.D. University of Maryland, Baltimore, 1899, a member of the Georgia Medical Society of Savannah, died at his home in that city, October 23, from Bright's disease, after a long illness, aged 28.

Sarah F. Mackintosh, M.D. Woman's Medical College of the New York Infirmary, 1872, died at her home in Asbury Park, N. J., October 19, aged 67. She was a member of the Monmouth County Medical Society.

Jonathan Taft, M.D. University of Michigan, Ann Arbor, 1881, founder and dean of the dental department of the University of Michigan, died at his home in Ann Arbor, October 15, after a short illness, aged 83.

Quincy E. Andrews, M.D. Jefferson Medical College, Philadelphia, 1865, an early settler of the Red River Valley, died at his home, eight miles north of Fargo, N. D., suddenly, from apoplexy, October 22, aged 69.

Benjamin Atkins Harding, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1870, died at his home in Blackstone, Ill., October 21, after an illness of ten days, from influenza, aged 61.

Daniel M. Schaeffer, M.D. College of Physicians and Surgeons, Baltimore, 1890, died from septicemia, after an illness of three weeks, October 21, at his home in Harper's Ferry, W. Va., aged 36.

Robert H. O'Hara, M.D. Jefferson Medical College, Philadelphia, 1865, died at his home in Williamstown, Ky., October 20, from kidney disease, aged 65. He retired from active practice in 1878.

Philip Roberts, M.D. Eclectic Medical Institute, Cincinnati, 1866, died at his home in Richmond, Ky., October 22, from paralysis, aged 70. He was twice state senator from his district.

William E. Waters, M.D., lieutenant colonel and deputy surgeon-general, U. S. Army, retired, died at his home in Washington, D. C., October 27, from acute gastritis, aged 69.

Laban C. Winsor, M.D. Bellevue Hospital Medical College, New York, 1885, died from consumption at his home in Livermore, Cal., October 21, after a long illness, aged 41.

Charles E. Decker, M.D., assistant surgeon U. S. P. H. and M.-H. Service, University of Michigan, Ann Arbor, 1891, died at his station in San Diego, Cal., October 22.

Asa Hopkins Churchill, M.D. Yale University, New Haven, 1867, a member of the Connecticut Medical Society, died at his home in Meriden, October 24, aged 72.

George W. Carpenter, M.D. University of Michigan, Ann Arbor, 1853, formerly of Chicago, died at his home in San Francisco, Cal., October 3, aged 87.

Zaremba W. Waldron, M.D. University of Pennsylvania, Philadelphia, 1871, of Jackson, Mich., died at Ann Arbor, Mich., October 1, from apoplexy, aged 60.

William B. Coyle, M.D. Queen's College, Belfast, Ireland, 1868, an early practitioner of Nelson County, N. Dak., died recently at his home in Lakota.

Benjamin Franklin Payne, M.D. Eclectic Medical Institute, Cincinnati, 1857, died at his home in Steubenville, Ohio, from paralysis, October 22, aged 76.

John W. Brown, M.D. Miami Medical College, Cincinnati, 1873, died at his home in Bailey, Texas, October 7, after a surgical operation.

Rose F. Monnish, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1882, died at her home in Atlanta, October 16.

Edwin Ashton, M.D. Cleveland Medical College, died at his home in Lima, Ohio, October 21, after an illness of four days, aged 77.

Lafayette Z. Coman, M.D. University of Michigan, Ann Arbor, 1879, died at his home in Boulder, Colo., October 18, from pneumonia.

Henry O. Hearn, M.D. Louisville Medical College, 1894, died at his home in Lexington, Ind., October 23, aged 35.

Emanuel Ridgeway, M.D. Chicago Medical College, 1878, died at his home in Morris, Ill., October 17, aged 71.

Deaths Abroad.

William Johnson Walsham, M.B., C.M., Aberdeen, 1871; F.R.C.S. England, 1875, successively assistant demonstrator of anatomy, demonstrator of anatomy, demonstrator of practical surgery, lecturer on anatomy and lecturer on surgery at St. Bartholomew's Hospital Medical School, London, one of the most eminent teachers of anatomy and surgery in Great Britain, died at his home in London, October 5, aged 56. His work on theory and practice of surgery reached an eighth edition before his death.

George Lawson, F.R.C.S. England, 1857, staff assistant surgeon throughout the Crimean War; surgeon to Middlesex Hospital, London, for 33 years; eminent as a specialist on the eye, and surgeon-oculist to the late queen, died at his home in London, October 12, after an illness of three years, aged 72.

James Robert Wallace, M.D., F.R.C.S., secretary of the Indian Medical Association; editor of the *Indian Medical Record*, died in Calcutta, September 27, after an illness of several months, following a severe attack of pleurisy.

Thomas James Pickburn, M.D. Aberdeen, 1874; M.R.C.S. England, 1876, one of the founders of the Hospital for Sick Children, Sydney, died from angina pectoris, at his home in that city, August 18, aged 57.

Osman F. Hall, M.D. Northwestern University Medical School, Chicago, 1896, a medical missionary in West China, died recently at his post of duty at Chung King, aged 37.

Book Notices.

TEXT-BOOK OF DISEASES OF THE EYE. For Students and Practitioners of Medicine. By Howard F. Hansell, A.M., M.D., Clinical Professor of Ophthalmology, Jefferson Medical College, and William M. Sweet, M.D., Demonstrator of Ophthalmology, Jefferson Medical College. With Chapters by Christian R. Holmes, M.D.; Casey A. Wood, M.D., D.C.L., and Wendell Reber, M.D. With 256 Illustrations, Including Colored Plates. Cloth. Pp. 532. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

This book is one that will be received with favor by the student and practitioner. It is a plain, clear statement of the principal facts of ophthalmology throughout, with a definition of terms that is clear, a description of conditions and methods that is at once concise and readily intelligible, and is a most satisfactory treatment of its very comprehensive subject. We find some matters here more easily explained with the aid of the illustrations and text than we have found them in some of the other text-books on the subject, and yet there is very little superfluous material. The illustrations are admirable and numerous. We notice certain additions, one of which seems to us a little novel in a work of this kind, though we presume that it has also been included elsewhere, that is, the chapter by Dr. Casey Wood on ocular symptoms in general diseases. The other two contributed chapters by Dr. Wendell Reber and Dr. Christian R. Holmes are also valuable. We

think, however, that perhaps a little more fulness in Dr. Reber's contribution might have been of some advantage; the brevity of the treatment is notable, though the subjects appear to be generally covered. Taken altogether the book is an excellent one and ought to be a success as an aid to teachers and as a ready reference book for general practitioners.

LESSONS ON THE EYE. For the Use of Undergraduate Students. Frank L. Henderson, M.D., Ophthalmic Surgeon to St. Mary's Infirmary. Third Edition. Cloth. Pp. 205. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1903.

Henderson has given us a valuable work. It is unique, as it teaches nothing but what the student and the general practitioner should know. No claim is made as to the correction to a fraction which can only be done by a trained specialist. The diseases described are such as do not require the use of the ophthalmoscope. Every teacher of ophthalmology will be pleased to place this work in the hands of his students. The illustrations are finely demonstrated and the work is presented in a very attractive form.

THE AMERICAN POCKET MEDICAL DICTIONARY. Edited by W. A. Newman Dorland, M.D., Assistant Obstetrician to the Hospital of the University of Pennsylvania. Containing the Pronunciation and Definition of the Principal Words Used in Medicine and Kindred Sciences. Pp. 566. With 64 Extensive Tables. Price, Flexible Leather, with Gold Edges, $1.00 net; with Thumb Index, $1.25 net. Philadelphia, New York and London: W. B. Saunders & Co. 1903.

This is a compact, handy and practical dictionary for the physician's office desk, or to place under the buggy seat. It contains practically every term used in medicine with concise definitions.

State Boards of Registration.

COMING EXAMINATIONS.

State Board of Examiners of Alabama, Montgomery, Nov. 1-10.

Oklahoma Medical Examining Board, Enid, Nov. 10.

Committee of the Connecticut Medical Society, City Hall, New Haven, Nov. 10.

Board of Registration in Medicine of Massachusetts, State House, Boston, Nov. 10-11.

State Board of Health of West Virginia, Point Pleasant, Nov. 10, 11, 12.

Nebraska State Board of Health, Lincoln, Nov. 11.

Board of Registration of Medicine of Maine, Augusta, Nov. 11.

Board of Medical Examiners of the State of California, City Hall, San Francisco, Dec. 1.

New Mexico Board of Health, Santa Fe, Dec. 7.

Examining Board of Medical Society of Delaware, Dover, Dec. 8.

Board of the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, Dec. 8.

Ohio State Board of Medical Registration and Examination, Columbus, Dec. 8, 9 and 10.

Kansas Report.—Dr. O. F. Lewis, Hepler, reports the written examination conducted by the Kansas State Board of Examination and Registration at Topeka, Oct. 13 to 15, 1903; the subjects examined in were 9; questions, 90; percentage, 75; candidates, 32; passed, 28; failed, 4.

The questions asked were as follows:

ANATOMY.

1. Give origin and insertion of the pectoralis major muscle. 2. Name all the muscles attached to the scapulæ. 3. What structures are severed in amputation of the thigh at the middle third? 4. Give origin and distribution of the pneumogastric nerve. 5. Give the coverings of an oblique inguinal hernia. 6. Give origin and insertion of the deltoid muscle. 7. Give the anatomy of the heart. 8. Give the number and names of the carpal and tarsal bones, respectively. 9. Give origin and distribution of the phrenic nerve. 10. Describe the structures within the eyeball.

CHEMISTRY.

1. What are molecules? 2. Is chlorin combustible or a supporter of combustion, and what occurs when a burning candle is immersed in chlorin? 3. What is nitrogen monoxid? 4. What is the chemical antidote for arsenical poisoning? 5. What is carbon dioxid, and what else is it called? 6. Where and how does sodium occur? 7. Does uric acid occur free in the urine normally. 8. What is the clinical significance of the presence of free uric acid in the urine? 9. Why do urates form deposits in joints and cartilages? 10. What is the reaction of blood during gout?

OBSTETRICS AND GYNECOLOGY.

1. What are the indications for the use of forceps? 2. Conditions requisite for the application of the forceps. 3. Under what conditions would you induce premature labor? 4. What is version? How many kinds are there? Name them. 5. How would you perform each kind of version? 6. How would you treat tumors of the mammary glands in a general way? 7. Give diagnosis, prognosis and treatment of fibroids of the uterus. 8. Give the use of the curette. 9. Give the use of the tampon. 10. How would you treat a case of puerperal eclampsia?

PATHOLOGY.

1. Define gangrene. 2. What is a sarcomatous tumor? Give its pathology. 3. Define chronic gastritis and give its pathology. 4. Give symptoms, etiology, pathology, diagnosis and prognosis of herpes zoster. 5. Give symptoms, etiology and prognosis of erysipelas. 6. Give etiology, symptoms, diagnosis and prognosis of neuritis (multiple). 7. Define lithemia. 8. Define purpura hemorrhagica. 9. Give differential diagnosis of septicemia and pyemia. 10. Describe the pathology of rachitis.

BACTERIOLOGY.

1. Define bacteria. 2. Name one cause of many fermentations. 3. Define germicides. 4. Name four germicides. 5. What does the presence of tubercle bacilli signify? 6. The presence of the Klebs-Loeffler bacilli in an exudate is positive evidence of what disease? 7. What are spores? 8. Name principal cause of poisoning from canned meats, milk and cheese. 9. In what disease do you find the streptococci? 10. Name the bacillus of diphtheria.

PHYSIOLOGY.

1. Give the history of the corpuscles. 2. Give the composition of the blood. 3. Give the phenomena of a simple muscular contraction. 4. Write a page on reflex action. 5. Give the main general facts of the circulation. 6. Describe the mechanism of the valves of the heart. 7. Describe the movements of the esophagus and stomach. 8. What change does the food undergo in the alimentary canal? 9. Give the source and distribution of heat in the body. 10. Write a page on the influence of the nervous system on nutrition.

SURGERY.

1. Give the etiology, diagnosis and treatment in traumatic gangrene. 2. What circumstances would lead you to expect erysipelas to become a factor in your surgical cases? What measure would you use to avoid it? and, if occurring, how would you combat it? 3. What symptoms would lead you to guard against tetanus, and how would you treat the case? 4. What would be your treatment in a severe case of chilblains? 5. Differentiate chancre from chancroid. 6. Describe the operation of hare-lip. 7. A boy, aged 8, fell onto his elbow and injured it severely and has no use of the joint. What is the most profitable pathologic condition, and how will you treat it? 8. Describe an amputation of the third finger at the metacarpo-phalangeal articulation. 9. What is whitlow, and how should it be treated? 10. Differentiate between talipes equinus and talipes valgus and give surgical treatment.

MATERIA MEDICA—REGULAR.

1. What are the regular preparations and doses of hydrastis? 2. What medicines are incompatible with the iron preparations? 3. What is the source from which phosphorus is obtained? 4. What is hyoscyamus? 5. What precautions should be observed in administering ether? 6. What are the physiologic effects of valerian? 7. What are the medicinal uses of veratrum viride? 8. What are antheimintics? 9. What is ammonium chlorid? 10. Name the sedative expectorants.

THEORY AND PRACTICE—REGULAR.

1. Diphtheria diagnosis, prognosis and treatment. 2. Purpura diagnosis and treatment. 3. Give diagnosis, prognosis and treatment of acute bronchial catarrh. 4. Write a page on the sounds of the heart. 5. Tell what abnormal sounds of the heart indicate. 6. Give diagnosis and treatment of acute peritonitis. 7. Name the chronic diseases of the liver. 8. Give the different steps in the examination of urine. 9. Write a page on epilepsy. 10. Chorea diagnosis and treatment.

THEORY AND PRACTICE—HOMEOPATHIC.

1. Describe a typical case of tabes dorsalis and name best treatment. 2. Name five leading remedies for pneumonia and give indications calling for each. 3. Give technical name, course and treatment of a typical case of spotted fever. 4. Differentiate between acute bronchitis and whooping cough in its early stages. 5. Locate and describe a typical case of appendicitis, naming best

treatment. 6. Give diagnosis and treatment of Bright's disease; also give technical name. 7. Differentiate between pleurisy and pleurodynica. 8. Describe a typical case of cholelithiasis, giving treatment. 9. Give diagnosis, prognosis and treatment of glycosuria. 10. Give the fundamental principles of the homeopathic practice, including scientific reason for giving infinitesimal doses.

MATERIA MEDICA—ECLECTIC.

1. Define the terms tonics, alteratives, sedatives and diaphoretics. Name five remedies in each class. 2. Define the terms antispasmodics, anthelmintics, diuretics, cholagogues, oxytoxics, and name five in each class. 3. What is the composition of stillingia liniment? (Scudder.) 4. Make a belladonna plaster. State where plant grows, when gathered, part used, how manipulated till in the plaster ready for use. 5. What drug plants are indigenous to the state of Kansas? 6. What is the composition and therapeutic property of King's diaphoretic powder, syrup mitchella compound, libradol, antibilious physic, and Mayer's ointment? 7. State the indications for the administering of bryonia, rhus, tox, macrotys, apis, viburnum, aconite, ipecac, echafolta, cactus, drosera, collinsonia, apocynum, nux vomica, podophyllum, hydrastis, sanguinaria, subnitrate of bismuth, sodium sulphite, muriatic acid and nitric acid. 8. What is the origin and therapeutic property of carbolic acid? 9. Name the different finished products of Peruvian bark; also of the Chinese poppy. 10. Name six common poisons and give their antidotes.

Minnesota Report.—Dr. C. J. Ringnell, Minneapolis, secretary of the Minnesota State Board of Medical Examiners, reports that some medical schools are unfamiliar with the rules of the board. All applicants must present evidence of having attended four full courses, extending over four years, at a medical college recognized by the Minnesota board. Candidates having been granted advanced standing for work done at non-medical colleges are not eligible. During the last year a considerable number have made application who have taken only a three years' course in the medical departments. At the examination in St. Paul October 6 to 8, 95 written questions were asked on 12 subjects and a percentage of 75 was required; out of 35 applicants, 23 passed and 13 failed. We have prepared a summary below of the schools having 2 or more representatives. All applicants are recent graduates (1900, 1901, 1902 or 1903) unless otherwise specified.

COLLEGE.	No. Passed.	No. Failed.	Max. Grade.	Min. Grade.	Average of Those Who Passed.	Average of Those Who Failed.
Hamline Univ., Minneapolis..	3	0	77.2	76.1	76.4	.....
University of Minnesota.....	3	2	84.7	71.1	80.5	72.2
Rush Medical College, Chicago	6	0	88.7	78.3	82.5	.....
Northwestern Univ., Chicago..	3	0	87.6	77.1	82.3	.....
Coll. Phys. and Surgs., Chicago	2	5	80.0	68.5	78.1	69.8
University of Iowa.....	1	1	77.4	*70.2	77.4	70.2
Hahnemann Med. Coll., Chicago	0	2	†70.5	65.5	.....	68.0
Chicago Homeo. Med. College.	2	0	‡80.1	77.8	78.9	.....

* Graduate 1891, second examination. † Graduate 1897, fourth examination. ‡ Graduate Chicago Homeopathic Medical College, 1896, and Rush Medical College, 1898.

Following are the grades in detail of the candidates from schools having three or more representatives:

Hamline University: 76.1, 77.2 (third examination), 76.1 (second examination).
Rush Medical College: 82, 82.8, 88.7, 78.3, 85, 78.4.
Northwestern University: 82.4, 87.6, 77.1.
University of Minnesota: 76.9 (second examination), 84.7, 80.1 (second examination), 71.1 (graduate 1899), 73.4 (second examination).
College of Physicians and Surgeons, Chicago: 80, 76.3, 68.5, 68.7, 68.6, 72.9, 70.4.

In addition there were the following applicants:

PASSED.

College.	Date Grad.	Per Cent.
McGill University, Montreal.....	1903	77.6
University of Michigan.....	1903	83.5
Omaha Medical College.....	1902	86.9

FAILED.

University of Vermont.....	1903	68.3
University of King Frederick, Norway.....	1902	55.6

The board's grades average as follows: Passing 81.0, failing 63.3, average of all 76.7.

The American Confederation of Reciprocating, Examining and Licensing Medical Boards.—A meeting of this board was held at the Southern Hotel, St. Louis, October 27. The meeting was well attended, representatives being present from Michigan, Wisconsin, Indiana, Illinois, Kentucky, Iowa, Nebraska and Missouri. The conference was called to consider "reciprocity from the standpoint of experience in the interchange of state licenses." This subject was discussed in all its bearings by the members of the confederation, as well as by a large number of visitors; among others, Dr. Carl Black, president of the Illlinois State Medical Society. It was the consensus of opinion of those present that interstate reciprocity in licensing physicians is urgently demanded by the medical profession, but that there are many obstacles in the way of a practical solution of the question. Among these are: A want of uniformity in the standards now and at the time licenses were issued; the fact that in many states licenses were formerly issued merely on presentation of a diploma, and are now issued only after a satisfactory examination before the state board of health or licensing board of the state; also that in many states, the laws strictly prohibit reciprocity; in others like Illinois, the law is silent on the subject, and in many states in which reciprocity is permitted by law, it is refused by the licensing body of the state. Most of the discussion of the afternoon was centered on qualification No. 2, which provided that "A certificate of registration, or license issued by the proper board of any state, may be accepted as evidence of qualification for reciprocal registration in any other state, provided that the holder thereof at the time of such registration was the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date thereof was prior to the legal requirement of the examination test in such state." This qualification was stricken out and a committee appointed to draft a new paragraph in its place. The provisions of qualification No. 2 as rewritten, do not differ essentially from those stated above, except that the word "thereof" was made to read "of such registration," in order that it might apply to the date of registration rather than the date of the diploma. Beyond the fact that the question was discussed from all sides and that a better understanding was had of the difficulties in the way of securing reciprocity, little of a substantial nature was accomplished. The following officers were elected: President, Dr. William A. Spurgeon, Muncie, Ind.; vice-presidents, Drs. Harris H. Baxter, Cleveland, Ohio, and John A. McKlveen, Chariton, Iowa; secretary and treasurer, Dr. Beverly D. Harison, Sault Ste. Marie, Mich.

The Public Service.

[For the benefit of the members of the medical departments of the Army, Navy, etc., this department is transferred from the last page, to allow the publication of each report one week earlier. The first and last pages of "The Journal" go to press before those in the center.]

Army Changes.

Changes in the Medical Department, U. S. Army, during the week ending Oct. 31, 1903:

Halliday, Francis A., contract surgeon, relieved from duty at Fort Moultrie, S. C., and ordered to Fort McPherson, Ga., for duty.

Wall, Francis M., contract surgeon, relieved from duty at Columbus Barracks, Ohio, and ordered to Camp George H. Thomas, Ga., for duty.

Harris, Herbert I., contract surgeon, relieved from duty at Camp George H. Thomas, Ga., and ordered to Columbus Barracks, Ohio, to accompany the Twentieth Infantry to the Philippines for duty.

Hart, James W., contract surgeon, relieved from duty at Fort Washington, Md., and ordered to Fort Hunt, Va., for duty.

Richards, Alfred, contract surgeon, relieved from duty at Fort Hunt, Va., and ordered to Fort Sheridan, Ill., to accompany the Twentieth Infantry to the Philippines for duty.

Hodson, Frederick A., contract surgeon, relieved from duty at Fort Mackenzie, Wyo., and ordered to San Francisco, to accompany the Twentieth Infantry to the Philippines for duty.

Ashburn, James K., contract surgeon, relieved from duty at Fort Crook, Neb., and ordered to Fort Lincoln, N. D., to relieve Contract Surgeon Samuel S. Turner, who will proceed to his home at Chicago for annulment of contract.

Hogan, David D., contract surgeon, has arrived at Mazomanie, Wis., on two months' leave of absence from the Division of the Philippines.

Jones, John F., contract surgeon, has been relieved from duty at Fort Schuyler, N. Y., and assigned to duty at Fort Totten, N. Y.

Mason, George L., contract dental surgeon, has been granted one month's leave of absence from the Division of the Philippines, with permission to travel in China.

The following named assistant surgeons, recently appointed, are ordered to report, on Nov. 3, 1903, at 9 o'clock a. m., at the Army Medical Museum Building, Washington, D. C., to Col. C. L. Heizmann, assistant surgeon general, president of the faculty of the Army Medical School, for a course of instruction at that school: First Lieuts. Craig R. Snyder, Ernest G. Bingham, James D. Heysinger, John B. Huggins, Edgar W. Miller, William H. Tafft, Lloyd L. Smith.

The following named assistant surgeons are relieved from duty at the post designated after their respective names and ordered to report at the Army Medical Museum, Washington, D. C., at 9 o'clock a. m., Nov. 3, 1903, to Col. C. L. Heizmann, assistant surgeon general, president of the faculty of the Army Medical School, for a course of instruction at that school: First Lieuts. Henry S. Klersted, Fort Miley, Cal.; Jay R. Shook, Fort Myer, Va.; Robert E. Noble, Fort Sheridan, Ill.; J. W. Van Dusen, Columbus Barracks, Ohio; Park Howell, Eagle Pass, Texas; R. B. Miller, San Francisco, Cal.; J. I. Mabee, Post of San Francisco, Cal.; P. L. Jones, Fort Rodman, Mass.; F. L. Palmer, Jefferson Barracks, Mo.; E. B. Vedder, Fort Columbus, N. Y.; Henry F. Pipes, Fort

Totten, N. Y.; C. L. Foster, Fort Myer, Va.; J. R. Bosley, Fort McPherson, Ga.; R. C. Loving, Fort Leavenworth; C. J. Sledman, Fort Adams, Miss.; O. G. Brown, Fort Monroe, Va.; G. F. Juenemann, Fort Columbus, Ohio; Joseph F. Siler, Fort McPherson, Ga.; Arthur Whaley, Fort Sheridan, Ill.

Thornburgh, R. M., first lieut. and asst.-surgeon, is relieved from duty at Fort Slocum, N. Y., and ordered to Fort Warren, Mass.

Mathews, George W., first lieut. and asst.-surgeon, is relieved from duty at Fort Warren, Mass., and ordered to proceed to Fort Dupont, Del.

Collins, George L., first lieut. and asst.-surgeon, resigned his commission as an officer, to take effect Oct. 23, 1903.

Webb, W. D., first lieut. and asst.-surgeon, reported for duty at West Point, N. Y., on Oct. 23, 1903.

Truby, W. F., first lieut. and asst.-surgeon, reported for duty at Fort Preble, Me., Oct. 24, 1903.

Ewing, Charles B., major and surgeon, relieved from duty at Fort Preble, Me., and ordered to Columbus Barracks, Ohio, reports his departure for new station Oct. 28, 1903.

McAndrews, P. H., first lieut. and asst.-surgeon, left Jefferson Barracks, Mo., for temporary duty at Fort Des Moines, Iowa, on Oct. 28, 1903.

Bevans, James L., first lieut. and asst.-surgeon, reported for duty at Morro Castle, Santiago, Cuba, Oct. 18, 1903, from Rowell Barracks, Cuba.

Wakeman, William J., major and surgeon, is granted thirty days' leave of absence.

Wales, P. G., major and surgeon, returned to station at Fort Assiniboine, Mont., from leave of absence.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Oct. 31, 1903:

P. A. Surgeon C. N. Fiske, commissioned passed assistant surgeon, with rank of lieutenant, from May 15, 1903.

Pharmacist E. T. Morse, detached from Navy Yard, Boston, and ordered to the Navy Yard, Portsmouth, N. H.

Medical Inspector D. N. Bertolette, detached from duty at Naval Dispensary, Washington, D. C., and ordered to continue other duty.

Surgeon F. L. Pleadwell, detached from the *Kearsarge* and ordered to duty at the Naval Dispensary, Washington, D. C.

Surgeon C. H. T. Lowndes, detached from Naval Hospital, Boston, and ordered to the Naval Academy, Annapolis, Md.

P. A. Surgeon J. J. Snyder, ordered to the *Kearsarge*.

Asst.-Surgeon Karl Ohnesorg, detached from the Naval Academy and ordered to the Naval Hospital, Boston.

Asst.-Surgeon H. A. Dunn, ordered to the Naval Proving Ground, Indian Head, Md.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Oct. 30, 1903:

SMALLPOX—UNITED STATES.

Illinois: Belleville, Oct. 10-23, 4 cases, 2 deaths; Chicago, Oct. 18-24, 1 case.

Maine: Bangor, Oct. 10-19, 50 cases; Brewer, Oct. 10-19, 10 cases.

Massachusetts: New Bedford, Oct. 18-24, 1 case.

Michigan: Detroit, Oct. 18-24, 1 case.

New Hampshire: Manchester, Oct. 18-24, 6 cases.

New Jersey: Jersey City, Oct. 19-25, 1 case.

New York: New York City, 18-24, 2 cases.

Ohio: Cincinnati, Oct. 17-23, 4 cases; Cleveland, Oct. 18-24, 1 death; Dayton, Oct. 18-24, 1 case.

Pennsylvania: Altoona, Oct. 18-24, 4 cases, 1 case imported; Johnstown, Oct. 18-24, 14 cases, 3 deaths; Philadelphia, Oct. 18-24, 9 cases, 8 deaths.

Utah: Salt Lake City, Oct. 18-24, 1 case.

Wisconsin: Milwaukee, Oct. 22-28, 2 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Oct. 4-10, 9 cases.

Colombia: Barranquilla, Oct. 5-11, 1 death.

Great Britain: Birmingham, Oct. 4-10, 6 cases; Bradford, Sept. 26-Oct. 10, 5 cases; Glasgow, Oct. 10-16, 5 cases; Leith, Oct. 4-10, 1 case; Liverpool, Oct. 4-10, 3 cases; London, Oct. 4-10, 2 cases; Manchester, Oct. 4-10, 2 cases; Newcastle-on-Tyne, Oct. 4-10, 4 cases.

India: Bombay, Sept. 16-29, 3 deaths.

Italy: Catania, Oct. 9-15, 1 death.

Netherlands: Amsterdam, Oct. 11-17, 3 cases, 1 death.

Russia: Moscow, Sept. 20-Oct. 3, 4 new cases, 7 deaths; Odessa, Oct. 4-10, 2 cases; St. Petersburg, Sept. 27-Oct. 3, 1 death.

Spain: Barcelona, Oct. 4-10, 5 deaths.

Venezuela: Bolivar, Oct. 4, present; San Felipo, Oct. 14, epidemic; Tucuyo, Oct. 3, prevailing.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Oct. 22-28, 95 cases, 10 deaths; Minera, Oct. 21-23, 3 cases, 1 death; San Antonio, Oct. 21-26, 7 cases, 1 case at Fort Sam Houston; Dewitt County, Oct. 26, 3 cases, 1 death.

YELLOW FEVER—FOREIGN.

Costa Rica: Limon, Oct. 1-15, 1 case.

Cuba: Habana, Oct. 6-9, 1 case on American S.S. Monterey from Progreso; 2 cases on German S.S. Prinz Adalbert from Vera Cruz and Tampico.

Mexico: Citas, Sept. 27-Oct. 3, 16 cases, 5 deaths; Linares, Sept. 27-Oct. 3, 555 cases, 46 deaths; Merida, Sept. 27-Oct. 3, 13 cases, 4 deaths; Nuevo Laredo, Oct. 22-27, 12 cases, 4 deaths; Tampico, Sept. 27-Oct. 3, 5 cases, 4 deaths; Vera Cruz, Oct. 10-17, 58 cases, 18 deaths.

CHOLERA—FOREIGN.

India: Madras, Sept. 19-25, 3 deaths.

Japan: Kobe, Sept. 26-Oct. 3, 2 cases, 1 death.

Turkey: Hama, Oct. 3, prevailing; Homs, Oct. 3, prevailing; Nabeck, Oct. 3, prevailing; Tripoli, Sept. 15, 15 to 20 cases daily.

PLAGUE—FOREIGN.

Australia: Queensland, Brisbane, Sept. 12, 2 cases, 2 deaths; Townsville, Sept. 4, 1 case, 1 death.

Chili: Iquique, May 15-Aug. 17, 170 cases, 101 deaths; Valparaiso, to Aug. 24, 9 cases, 2 deaths.

Japan: Yokohama, Sept. 13-26, 2 cases, 1 death.

Medical Organization.

Indiana.

LAKE COUNTY MEDICAL SOCIETY.—This society has been reorganized at Hammond with the aid of Dr. George F. Keiper, Lafayette, councilor for the Tenth District, with Dr. Frederick Howat, Hammond, president.

Iowa.

POWESHIEK COUNTY MEDICAL SOCIETY.—Physicians of the county met in Grinnell, October 9, and formed a county society on the standard plan with the aid of Drs. Edward E. Dorr, Des Moines, and David C. Brockman, Ottumwa, councilors for the Seventh and Sixth districts, respectively. The following officers were elected: President, Dr. Elbert W. Clark, Grinnell; vice-president, Dr. Edward B. Williams, Montezuma; secretary and treasurer, Dr. Pearl E. Somers, Grinnell, and censors, Drs. Samuel C. Buck, Grinnell, Charles D. Busby, Brooklyn, and Vinton S. Wilcox, Malcom.

Louisiana.

VERNON PARISH MEDICAL SOCIETY.—This society was recently organized in affiliation with the state and national organizations and elected the following officers: Dr. Mark R. McAlpin, Leesville, president; Dr. C. C. Self, Hornbeck, vice-president; Dr. Frederick W. Dortch, De Ridder, secretary, and Dr. James H. Word, Leesville, treasurer.

LAFOURCHE PARISH MEDICAL SOCIETY.—Physicians of the parish met at Thibodaux, October 24, and organized a parish society with an initial membership of 14. Dr. John M. Barrier, Delhi, president of the Louisiana State Medical Society, was present and aided in the organization, which was effected on the standard plan. Dr. Albert J. Meyer, Thibodaux, was elected president; Dr. Abel J. Price, Lockport, vice-president, and Dr. Sampson A. Ayo, secretary and treasurer.

Wisconsin.

MARQUETTE COUNTY MEDICAL SOCIETY.—Physicians of the county met at Packwaukee, September 8, and organized a county society on the standard plan, with the following officers: Dr. William J. Thomson Briggsville, president; Dr. Edward A. Bass, Montello, vice-president; Dr. William O. Dyer, Westfield, secretary and treasurer, and Drs. Thomas Lucast, Endeavor, William O. Dyer, Westfield, and Edward A. Bass, Montello, censors.

Society Proceedings.

COMING MEETINGS.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.

Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 15.

Western Surgical and Gynecological Association, Denver, Dec. 28-29.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Proceedings of the Thirty-first Annual Meeting, held at Washington, D. C., Oct. 26 to 30, 1903.

The association met in the assembly hall of the New Willard Hotel under the presidency of Dr. Walter Wyman, Surgeon-General of the U. S. Public Health and Marine-Hospital Service, Washington, D. C. The session was well attended and great interest was shown in the various subjects discussed.

Opening Address.

GEN. GEO. M. STERNBERG, in the opening address, referred to the association as an important factor in promoting the welfare of the people of the United States, not only from a sanitary point of view, but also in the way of national prosperity. After speaking of the present status of yellow fever, he discussed the incomplete sewage and water systems of the

city of Washington. The high death rate from typhoid fever, tuberculosis and diphtheria and the excessive infant mortality among the lower classes give to the Nation's capital a mortality rate which does not compare favorably with that of many other cities in this country or in Europe. A law for the condemnation of unsanitary houses is urgently needed. The sewer system should be pushed to completion and the health department should have the authority and the money necessary for the sanitary reclamation of the plague spots which disgrace an otherwise beautiful and healthful city.

Address of Welcome.

This was delivered by Hon. H. B. F. Macfarland, president of the Board of Commissioners of the District of Columbia. He referred to the work of improving the water supply and sewer systems of Washington which is in progress, and also the effort being made to secure legislation to enable the city to end the unsanitary conditions in its slums. It is fully realized that the health of the people is the first duty of the statesman, and that all else that can be done for this or any capital goes for nothing if its health is not protected and promoted.

President's Address.

Following Mr. Macfarland's welcome, Surgeon-General Wyman delivered his annual address, which will be printed in THE JOURNAL.

Report of the Committe on Car Sanitation.

This report was read by the Chairman, Dr. Granville P. Conn, Concord, N. H. The committee had no reforms to suggest that would at once settle the much-vexed question, but progress was being made, the opinions of the railroad managers were being molded and the problem was gradually being solved. The travelers have but little or no thought of the sanitation or well-being of those who may be the next passengers to occupy the same seats. The more permanent the means and methods adopted by health authorities, the more satisfactory they will prove to the commercial world and to the general manager.

Transportation of Persons Sick with Transmissible Diseases.

DR. J. N. HURTY, Indianapolis, read a paper with this title. Public opinion will not tolerate the transportation in railway trains of cases of smallpox, yellow fever, bubonic plague, diphtheria, scarlet fever and leprosy. An understanding of the dangers from pulmonary tuberculosis, influenza and typhoid fever would develop a public opinion demanding of patients having these diseases that rational regulations intended to prevent transmission must be rigidly enforced. Special compartments for persons sick with communicable diseases are impracticable.

Car Sanitation in the Republic of Mexico.

DR. JUAN BREÑA, Zacatecas, Mexico, said that since infectious germs float in the air and are deposited on moldings and ornaments and are thence again taken up by the air and inhaled, simplicity of ornamentation and smooth polished surfaces have been again and again recommended. He discussed the fittings of railway coaches and urged that, in spite of the lack of attention paid to these suggestions, sanitarians should continue to work for the proper hygienic equipment of railway coaches.

Immigration and Public Health.

DR. A. J. MCLAUGHLIN, Washington, D. C., said that in considering the danger to the public health from immigration three factors must be taken into account. 1. The physique of the immigrant. 2. His destination. 3. The presence or absence of communicable disease. The physique of the immigrant is by far the most important factor. Aliens of a race having a low physical standard almost invariably herd together in the overcrowded, unsanitary tenement districts of the great cities; while the sturdy races of unskilled laborers are scattered over a wide territory and tend to establish homes in the country or in the suburbs of manufacturing towns.

Certain loathsome and dangerous contagious diseases exist among immigrants, and constant vigilance and considerable skill are necessary to detect them. The most important, because of its frequency, is trachoma. Of the total number of cases of loathsome or dangerous diseases found in immigrants, 87 per cent. are due to trachoma, and 10 per cent. to favus.

The writer concluded that if the thousands of recruits for the sweat-shop army who arrive each year could be checked for ten years the present existing tenement-house problem would solve itself. The terrible congestion of the tenements would be relieved; the scale of wages for the sweat-shop worker would be elevated, and the general sanitary conditions of life in such districts as in the lower east side, New York City, improved sufficiently to reduce the menace to the public health from this cause to a minimum.

New Officers.

The following officers were elected: President, Dr. Charles J. Finley, Havana, Cuba; vice-presidents, Drs. J. R. Monjaras, Mexico, and W. W. Woodward, Washington, D. C.; secretary, Dr. Charles O. Probst, Columbus, Ohio; treasurer, Dr. Frank W. Wright, New Haven, Conn. The next annual meeting will be held at Havana, Cuba.

(To be continued.)

NEW YORK STATE MEDICAL ASSOCIATION.

Twentieth Annual Meeting, held in New York City, Oct. 19-22, 1903.

(Continued from page 1108.)

School Hygiene and the Great Need of Regular Medical Supervision.

DR. H. ERNST SCHMID, White Plains, presented a paper urging all physicians to do their full duty as enlightened citizens and showing how much they might accomplish. He said that the classroom should have a seating capacity of forty pupils with light entering at the side or the side and back, with glass space equal to one-fourth or one-third of the floor space, and with shades working from the bottoms of the windows. The walls should be greenish-gray. He hoped the medical profession would use its influence to secure the passage of a law requiring all schools of the state to be under constant medical supervision.

Sea Bathing.

DR. R. ABRAHAMS, New York, advised sea bathing for pityriasis versicolor, chronic eczema and senile pruritus, and claimed that the results were good, and totally different from those obtained by using salt water in a bathing establishment.

Bacteriology and Pathology of Dysentery in Children.

DR. WILLIAM H. PARK, New York, discussed this subject. He said that the investigations of the past summer showed that there were several types of cases in that locality, and that cultures from these ordinarily showed a bacillus known as the acid type. The Shiga bacillus was only found occasionally. About 50 cases had been observed, and the serum treatment used in one-half. No very striking results had been obtained, and such improvement as was observed was mainly in the severe cases; nevertheless he thought increasing experience and knowledge would show that the method was worthy of trial. Hitherto it had been assumed that there was but little difference between the two types of bacilli, and that one serum would do for both. By the production of a serum of a wider range of usefulness it was hoped for a corresponding improvement in the results.

Some Less Usual Causes of Post-Operative Elevations of Temperature.

DR. MARTIN B. TINKER, Clifton Springs, in this paper mentioned among other causes small pulmonary emboli, pericarditis, cerebral embolus, phlebitis and thrombosis affecting the saphenous veins and last, but not least, malaria. The last mentioned should not, however, be diagnosticated unless supported by the detection of the plasmodium in the blood.

Laboratory Aids to Diagnosis for the General Practitioner.

DR. V. A. ROBERTSON, Brooklyn, said that, aside from the cost of the microscope, the expense of fitting up a laboratory

for the physician was slight, and one would be well repaid for the moderate outlay. Examination of sputa for tubercle bacilli and pneumococci, of the blood for leucocytosis and for the malarial organism, and of the feces in dysentery were examples of the many ways in which the laboratory could aid the practitioner.

Treatment of Puerperal Sepsis.

Dr. James Hawley Burtenshaw, New York, in a paper on this subject, opposed sharp curettage. Lacerations should be cauterized and the uterus irrigated, after which a packing of 10 per cent. iodoform gauze should be inserted. Ergot, strychnin, quinin and alcoholic stimulants are indicated, with nutritious diet.

DISCUSSION.

Dr. Joseph B. Cooke, New York, called attention to the value of holding the fundus of the uterus after confinement as a prophylactic measure.

Dr. E. V. Delphey, New York, favored using a postpartum douche of hot iodin water as a preventive, and in septic cases, the administration of digitalis.

Dr. DeLancey Rochester of Buffalo spoke of the value of iodin locally before labor, and of iodin water after delivery in cases of known gonorreal infection.

When and How to Operate for Gallstones.

Dr. Irving S. Haynes, New York, read a paper with this title. He said that whereas late operations usually had a death rate of 40 per cent., early operations were almost always successful. In endeavoring to make an early diagnosis it should be borne in mind that biliary colic and jaundice were commonly absent, and that the patient would probably complain of digestive disturbance, with a dull pain and perhaps some tenderness in the vicinity of the gall bladder. Ochsner found jaundice absent in 75 per cent. of his cases. The pain is usually referred to the epigastrium and there is often a point of tenderness an inch and a half to the right and above the umbilicus. Severe colicky attacks are absent in about half of the cases. As ideal conditions are rarely present the surgeon is often called on to simply incise and drain the gall bladder.

The Past and Present Needs of the Medical Profession.

Dr. Frederick Holme Wiggin, in his presidential address, thought it would be very useful if our medical schools would teach their students something of the history of medicine. The profession sadly needs organization, but if this is to be done properly, physicians must have a better understanding of the fundamental principles of organization and possess a deeper sense of individual responsibility. The organization of the future must be powerful enough to check the further demoralization of the public by a continuance or extension of the abuse of medical charity; it must discountenance contract practice at ruinous rates and must defend its members against unjust attacks on their professional honor and standing. The American Medical Association should be incorporated by the national government in order not only to give the necessary dignity but to facilitate the transaction of business in any state. The American Medical Association should at stated intervals publish a national medical directory from data furnished by the component societies. A great step ahead had already been taken by the agreement of the two state medical organizations of New York to combine into a society worthy of the Empire State.

Sewage Disposal as a Means of Purifying the Water Supply of the Cities and Towns of the State.

Dr. Charles B. Tefft, Utica, showed how easy and inexpensive it is for even the farmer to protect himself and his neighbors by means of an apparatus for intermittent sand filtration.

The Treatment of Pneumonia.

Dr. DeLancey Rochester, Buffalo, in this paper, laid down the following indications for treatment: (1) To relieve toxemia; (2) to prevent failure of the heart, and (3) to meet complications as they arose. The first indication was met by the use of foot baths or other means of securing free sweating without disturbing the patient, and by giving a daily dose of a saturated solution of sulphate of magnesium. A careful physical examination of the chest should be made at every visit in order that the physician may have early warning of the occurrence of pulmonary congestion. Should this occur, it could often be checked by prompt and vigorous use of wet or dry cups or by venesection. The cups should be left on for half an hour and should be reapplied at intervals of four or six hours. The poultice jacket should be relegated to the dark ages. When the heart threatened to fail, saline infusion or hypodermoclysis should be resorted to, and this might be reinforced by the hypodermic use of strychnin, or the administration of alcohol by the mouth. If the alcohol caused excitement, ammonia should be substituted. If the bowels and skin were kept active, hypnotics would rarely be required. As an evidence of the value of the treatment thus outlined, Dr. Rochester said that there had only been 23 deaths in 210 cases.

DISCUSSION.

Dr. A. Alexander Smith, New York, preferred venesection to cupping because less disturbing to the patient. He had given both the salicylate and the creosote treatment of pneumonia a fair trial, and had obtained only negative results from the former, while the latter had only proved of benefit in cases associated with general bronchitis. He did not like to give the plunge bath to pneumonia patients, but did favor the use of a wet pack at 80 F. or higher. He believed oxygen to be a valuable therapeutic agent in pneumonia, and nitroglycerin and other vasodilators of value when cyanosis was present.

Dr. W. P. Northrup, New York, spoke strongly against the still common custom of applying a jacket poultice. Such an application was particularly unsuitable in the case of weak and feverish children. The plunge bath had proved useful in his hands in the treatment of alcoholic pneumonia.

Dysmenorrhea.

Dr. Charles Bonifield, Cincinnati, after enumerating the causes, said that if the pain is in the hypogastric region, it points to a uterine origin; if the suffering is greater during the flow there is probably a constitutional cause. If the pain is in the iliac region, disease of the adnexa may be inferred. The coal-tar products are useful in these cases, and a combination of atropin and sodium bromid had been very successful in his hands. When there is defective development, dilatation of the cervix, curettement and packing of the uterus are indicated.

(To be continued.)

MANILA MEDICAL SOCIETY.

Regular Monthly Meeting, held at the Government Biological Laboratory, Sept. 7, 1903.

The meeting was a very enthusiastic one and was largely attended. There were 46 physicians present, probably the largest body ever gotten together in the Philippine Islands for scientific deliberation. The following papers were read:

Protective Inoculation Against Cholera.

Dr. R. P. Strong considered this subject under several headings, briefly summarized as follows: The work previously done on artificial immunity by Ferran, Haffkine, Kolle, Buchner, Metchnikoff, Roux and others was considered. While it is admitted that Haffkine's method, when properly applied, gives rise to good immunity in the inoculated, the local reaction is too great for the method ever to come into general use. Subcutaneous injection of either living or dead cholera vibrios produces more marked general symptoms and local reaction than does the injection of either killed plague or typhoid bacilli. The location of the specific toxin was next considered and evidence brought forward to show that the substance existed as an integral part of the living organism, and was set free only by the death of the same. In the author's form of inoculation, the cholera "receptors" were obtained from bodies of the bacteria by means of autolytic digestion. The proteolytic ferment produced by this organism brings about this result in a very satisfactory manner. This ferment is not destroyed at 60 C., and, therefore, the bacteria may be killed by careful heating from one to two hours and digested from two to five

days by this ferment, and then passed through a Reichel filter. Such a filtrate when injected into animals gives rise to autotoxic, bactericidal and agglutinative substances in their blood serum, and, moreover, protects them from the injection of fatal doses of living cholera spirilla. As the local reaction produced is very mild, such a filtrate offers itself as a practical form of protective inoculation in man. This filtrate may be evaporated and used in powdered form.

Tropical Influence on Diseases of the Oral and Dental Tissues.

Louis Ottofy, D.D.S., brought out the following points in his paper: In natives the diseases of the soft tissues of the mouth show no marked variation from diseases of the same tissues in other climates. The teeth of native children, as shown by statistical comparison with the teeth of Americans, Germans, English, etc., show the same proportion of caries as exists in the latter. In adults, the condition is said to be better, partly due to smoking, a habit acquired early and indulged in by both sexes. Their teeth are subject to betel erosion, due to chewing betel nut. Unacclimated foreigners are subject to considerable derangement of the system and likewise of the soft tissues of the mouth, among them a form of ulcerative stomatitis termed stomatitis ulcerativa tropica. The soft tissues, as a rule, yield more slowly to treatment, which is also true of diseases of the dental pulp, alveolar abscess, etc. The influence on the teeth themselves is only slight, and becomes almost *nil* with complete acclimatization. In the case of acclimated foreigners, aside from liability to diseases and their slower termination, no special differentiating features are noticeable.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Treatment of Gonorrhea.

W. H. Whitehead, in *Ther. Gazette*, states, when a patient comes to him with an acute case of gonorrhea, that he instills into the urethra a salve rather than an astringent wash. He instructs the patient to instill one-half a dram of the following after urinating:

℞.	Hydrarg. ovidi flavi	gr. xx	1 | 30
	Acidi oleici	ʒi	30 |
	Argenti oxidi	ʒii	8 |
	Pulv. pepsini		|
	Pulv. caroid, āā	ʒiv	15 |
	Albolini		|
	Lanolini		|
	Aquæ, āā	ʒii	60 |

M. Sig.: One-half a dram to be introduced into the urethra night and morning.

Absorbent cotton is then placed over the penis to catch the salve that returns; tie it loosely and instruct the patient to keep it on until he is compelled to urinate.

Internally he gives the following:

℞.	Olei santali	ʒiv	15 |
	Pulv. cubebæ		|
	Acidi benzoici, āā	ʒi	30 |
	Pulv. pepsini	ʒiv	15 |

M. Ft. cachets No. xxx. Sig.: One before meals and at late bedtime.

In preparing the salve the oxid of mercury and silver must be rubbed up together and then dissolved in the oleic acid and later adding the liquid albolene; then add the lanolin, and finally dissolve the pepsin and caroid in the water and filter through absorbent cotton and add to the salve and triturate until a creamy mass is obtained. Care must be observed in the mixing in order to obtain a smooth salve.

The salve, according to the author, is penetrating because of the presence of the liquid albolene, and germicidal owing to the mercury and silver. It digests the fibrous exudates out of the follicles and permeates the inaccessible germ-infected recesses. He claims, by this method of treatment, that he seldom has a backward extension as so frequently occurs under irrigation and injection treatment. The salve is painless and all discharge is arrested by a two or three days' use of it. When the discharge ceases and the urine becomes clear the local treatment is suspended, but the interval treatment is continued for ten days. If the discharge returns the salve will soon check it. In treating a female use the salve in larger quantities, but only once a day, putting a plug of cotton saturated with the salve well up in the vagina, if it alone is involved, and allow it to remain for twenty-four hours. Instruct the patient to remove it and take a hot salt-water douche just previous to her taking another application. If her urethra is involved the internal treatment should be given also, and also deposit the salve into the urethra once a day. The results of the treatment in the female is even more satisfactory than in the male.

Lead Colic.

The medicinal treatment, according to Yeo, consists in: 1. Relieving the constipation and pain. 2. In promoting elimination of the lead from the body. To relieve the pain the following is recommended:

℞.	Linimenti opii		|
	Linimenti belladon., āā	ʒss	15 |

M. Sig.: To be rubbed in freely around the navel.

An enema of soap and water, one or two pints, to which has been added an ounce (30.00) of castor oil, one half ounce (15.00) of turpentine and twenty minims (1.30) of laudanum, should be given in some cases to relieve the pain and increase the elimination. The following is recommended by the author as an aperient:

℞.	Mag. sulph.		|
	Sodii sulph., āā	ʒiss	45 |
	Acidi sulphurici arom.	3i	4 |
	Syr. zingiberis	ʒss	15 |
	Aq. cinnamomi q. s. ad	ʒxii	360 |

M. Ft. mistura. Sig.: Four teaspoonfuls every hour until bowels have moved thoroughly.

To procure elimination potassium iodid must be given combined as follows:

℞.	Pot. iodidi	gr. xl	2 | 65
	Mag. sulph.	ʒi	30 |
	Tinct. nucis vom.	3ii	8 |
	Aq. cinnamomi q. s. ad	ʒviii	240 |

M. Ft. mistura. Sig.: Two tablespoonfuls night and morning.

The following mixture containing alum is recommended by Bartholow in the treatment of lead colic:

℞.	Alumenis	3ii	8 |
	Acidi sulphurici	3i	4 |
	Syr. limonis	ʒi	30 |
	Aquæ q. s. ad	ʒiv	120 |

M. Sig.: One tablespoonful every two hours.

The following treatment has also been recommended for the treatment of lead colic:

℞.	Pulv. opii	gr. 1/4	| 015
	Ext. belladonnæ	gr. 1/12	| 005

M. Sig.: One such pill every two hours for twenty-four hours.

And the following purgative:

℞.	Sodii sulph.	3ii	8 |
	Mag. sulph.		|
	Syr. rubi idaei, āā	ʒss	15 |
	Aquæ	ʒiii	90 |

M. Sig.: At one dose, to be repeated as necessary.

Puerperal Insanity.

The *Amer. Jour. Med. Sciences* gives an abstract of the treatment of puerperal insanity as recommended by E. W. White in *British. Med. Jour.* As soon as the premonitory symptoms are observed, according to this author, such as change in manner and feelings, quiet surroundings must be obtained and skillful supervision enforced to guard against infanticide or suicide. Enemata and milk aperients should

be given for the bowels and the following combination given at night for the insomnia:

℞. Pot. brom.
Chloralis hydratis, āā.....gr. xxx 2
Elix. simplicis .....ʒss 15
M. Sig.: At one dose.

The foregoing may be repeated twice or three times daily if acute maniacal symptoms are present, guarding against overdosing. Later on the following mixture may be substituted as a hypnotic:

℞. Trional .....gr. xx-xxx 1.30-2
Paraldehyde .....ʒiss-ii 6-8
M. Sig.: At one dose for sleep.

Opium preparations should be avoided, unless the mental symptoms, when well established, are of a maniacal character, when opium preparations are given along with proper stimulants. He recommends in such conditions the following combination:

℞. Liq. morph. acetatis (1 per cent.)....m. xx 1|30
Spts. etheris .....m. xv 1
Aquæ camphoræ .....ʒi 4
M. Sig.: One such dose three times a day.

Every effort should be made to re-establish the suppressed menstrual flow, such as the administration of iron, hot baths, aloes and ergot. Olive oil will aid in preventing loss of weight, as will alcohol.

Migraine.

Ratchvord, in *Medicine*, recommends the following combination in the treatment of migraine:

℞. Sodii sulph. .....ʒss 2
Sodii salicylatis .....gr. x |65
Mag. sulph. .....gr. l 3|30
Lithii benzoatis .....gr. v |30
Tinct. nucis vom. .....m. iii |20
Aquæ destil. .....ʒiv 120
M. Sig.: To be placed in a siphon bottle and carbonated, and a small amount, sufficient to produce a laxative effect, taken daily before breakfast.

Erysipelas.

As a local antiseptic dressing in the treatment of erysipelas the following is recommended by Stroell in *Amer. Med.:*

℞. Acidi carbol.
Tinct. iodi, āā.....gr. xv 1
Mucil. acaciæ .....ʒi 4
Alcoholis (pure) .....ʒv 20
M. Sig.: Shake and paint over the affected area every two hours until the swelling and shiny redness have disappeared.

Acute Rheumatism.

The following combination, according to Peabody, is of value in the treatment of acute rheumatism:

℞. Acidi salicylici .....ʒss 15
Ferri pyrophos. .....ʒi 4
Sodii phosphatis .....ʒx 40
Aquæ .....ʒvi 180
M. Sig.: One tablespoonful every two hours well diluted in water.

Eye Bruises.

The following combinations are recommended by *Merck's Archives* in the treatment of "black eye":

℞. Ammon. chloridi
Alcoholis, āā.....ʒi 30
Aquæ .....ʒx 300
M. Ft. lotio. Sig.: Apply locally; or:
℞. Acidi acetici dil. .....ʒv 150
Tinct. arnicæ .....ʒi 30
Ammon. chloridi .....ʒi 30
Aquæ .....ʒv 150
M. Ft. lotio. Sig.: Apply locally; or:
℞. Pot. nitratis .....gr. xv 1
Ammon. chloridi .....ʒss 2
Acidi acetici dil. .....ʒiv 15
Aquæ q. s. ad.....ʒviii 240
M. Sig.: To be locally applied.

In burns the following combinations are recommended by the same periodical:

FOR BURNS OF THE FIRST DEGREE.

℞. Thymol .....gr. x |65
Olei lini .....ʒiv 120
Sodii bicarb. .....ʒii 60
Aquæ calcis .....ʒiv 120
M. Sig.: Shake, cover the affected areas liberally with this preparation and cover with borated cotton; or:
℞. Ext. opii .....gr. v |30
Ichthyol
Liq. petrolati
Lanolini, āā.....ʒiii 12
M. Sig.: Apply on lint.

If the burns are extensive the amount of opium should be diminished.

FOR BURNS OF THE SECOND DEGREE.

℞. Airol .....ʒi 4
Lanolini (anhydrous)
Vaselini, āā.....ʒiv 15
M. Sig.: Apply locally.

[Airol is bismuth oxyiodogallate. It is an odorless, grayish-green powder, tasteless insoluble in water or alcohol. It is a valuable local antiseptic.]

℞. Xeroform .....ʒi 4
Olei lini .....ʒiiss 10
Solutionis plumbi subacet. .....ʒiss 6
M. Sig.: Apply freely on gauze.

FOR BURNS OF THE THIRD DEGREE.

℞. Ichthyol .....gr. xlv 3
Olei olivæ .....ʒiiss 10
Liq. petrolati
Lanolini, āā .....ʒix 270
M. Sig.: Apply locally.

Lactic Acid in Pruritus.

M. de Castle, according to an abstract in *Med. Rev. of Reviews*, has found that general pruritus in children rapidly disappears on the administration of lactic acid internally. He recommends it in doses of minims fifteen (1.00) daily, and for small children minims ten to fifteen (.65-1.00) of a 1 per cent. solution in divided doses during the twenty-four hours.

Chorea in Children.

The following outline of treatment is recommended by *Jour. des Pract.* in the treatment of chorea:

℞. Antipyrini .....ʒiiss 10
Syr. aurantii corticis.....ʒviii 240
M. Sig.: One dessertspoonful every two hours.

In addition the following should be given in the form of a suppository:

℞. Quin. hydrobrom. .....gr. ivss |27
Ol. theobromæ q. s.
M. Ft. suppos. No. i. Sig.: One such to be introduced at night in cases of children 6 years of age or older.

The substitution of arsenic for antipyrin is recommended at the end of a week or ten days:

℞. Sodii arsenatis.....gr. 1/3 |02
Aq. destil. .....ʒviii 240
M. Sig.: One dessertspoonful, well diluted, twice daily after meals.

The use of the cold pack and tepid baths are also recommended in the treatment of chorea.

Malbec, in *La Med. Moderna*, advises the following combinations in the treatment of chorea:

℞. Salipyrini .....ʒiiss 10
Strontii brom. .....ʒv 20
Syr. aurantii corticis .....ʒiii 90
Aq. calcis .....ʒvi 180
M. Sig.: One teaspoonful in water after each meal.

The following may alternate with the above or substitute it:

℞. Ferri glycerophos. .....gr. lxxv 5
Syr. aurantii corticis .....ʒiii 90
Vini quininæ
Vini kolæ, āā.....ʒvi 180
M. Sig.: One wineglassful after each meal.

[The wine of kola and of quinin are not standard preparations.]

Medicolegal.

SOME LEGISLATION OF THE YEAR 1903.

Kansas—Prohibition as to Exhibitions of Hypnotism.—Chapter 219 of the Laws of Kansas of 1903 provides that any person who shall induce or permit any child under 18 years of age to practice or assist or become a subject in giving public exhibitions of hypnotism, mesmerism, animal magnetism or so-called psychical forces shall be guilty of a misdemeanor, and on conviction be fined or imprisoned, or both.

Kansas—Prohibition of Marriage in Certain Cases.—The bill to prevent marriage of defectives, given in full on pages 788 and 789 of THE JOURNAL, March 21, 1903, is made Chapter 220 of the Laws of Kansas of 1903, entitled "An act regulating marriage and prohibiting marriage by or with persons afflicted with imbecility, feeble-mindedness, epilepsy or insanity, and prescribing penalties . . ." for violation of the act.

Kansas—Authorizes Temporary Permits to Practice.—Chapter 358 of the Laws of Kansas of 1903 provides that the secretary of the State Board of Medical Registration and Examination may in his discretion issue a temporary permit to practice medicine or surgery to any person who shall have made application in writing to said board for license to practice, accompanied by the prescribed fee, and proof as required by Section 3 of Chapter 254 of the session laws of 1901, and who shall be a graduate of any legally chartered medical institution of the United States or any foreign country; or such permit may be so issued to any such applicant for license, complying with said conditions, who is shown to have been licensed by the board of registration and examination in any other state or territory of the United States or any foreign country whose standards of qualification for practice are equivalent to those of Kansas. Any such temporary permit so issued shall, when recorded in the office of the county clerk of the county in which he resides, authorize the person receiving the same to practice in the same manner as a permanent license up to the next regular meeting of the board; provided, that not more than one temporary permit shall be issued to any one person, nor shall any permit be extended beyond the time herein limited.

Nebraska—Control of Contagious Diseases.—Chapter 59 of the Laws of Nebraska of 1903 provides that the State Board of Health shall have supervision and control of all matters relating to the protection of the people of the state from contagious, infectious and epidemic diseases. It shall make careful inquiry into the cause of the various contagious, infectious, epidemic and endemic diseases, and shall take prompt action to suppress and control the same. The reports of births and deaths, the sanitary conditions of localities and of employments, the personal and business habits of the people and the relation of the diseases of beast and man shall be the subject of careful study by the board, and it shall make and enforce orders necessary to protect the people against diseases of lower animals. It shall collect and preserve such information as may be useful in the discharge of its duties, and for dissemination among the people. It shall be the duty of all boards of health, and of physicians in localities where there are no health authorities, or where such health authorities fail to act, to report to it promptly on the discovery thereof, the existence of Asiatic cholera, yellow fever, smallpox, scarlet fever, diphtheria, typhus and typhoid fever, and such other diseases as it may from time to time specify.

Nebraska—Grounds for Revocation of License.—Chapter 61 of the Laws of Nebraska of 1903 amending Section 14 of Article I of Chapter 55 of the compiled statutes, title "Medicine," provides that the board may refuse to issue a certificate or may revoke one already issued for any of the following causes: The employment of fraud or deception in applying for license on diploma or in passing the examination provided for in this act; conviction of crime involving moral turpitude; habitual intemperance in the use of ardent spirits, narcotics or stimulants; unprofessional or dishonorable conduct. The words "unprofessional or dishonorable conduct," as used herein, are declared to mean: First, the procuring or aiding in procuring a criminal abortion; second, the obtaining of a fee on the assurance that a manifestly incurable disease can be permanently cured; third, betrayal of a professional secret to the detriment of a patient; fourth, causing the publication and circulation of advertisements of any medicine or means whereby the monthly periods of women can be regulated or the menses can be established, if suppressed; fifth, causing the publication and circulation of advertisements of any kind relative to diseases of the sexual organs tending to injure the morals of the public.

5 Tubal Pregnancy; Report of Cases. Mary D. Rushmore.

1. **Conservatism of Ovaries and Tubes.**—After discussing the reproduction of defectives and advocating legislative restriction of marriage of defectives, Ferguson describes the operation of hysterosalpingostomy and salpingostomy. The indication for the former is an obstruction of the proximal end of the fallopian tube due to chronic inflammation or myoma. Age must be considered. Only patients in the reproductive periods of life should be operated on, and even if near the menopause the power to become pregnant should be retained. There would be no object in performing the operation where both ovaries are destroyed. The first thing is to determine whether the tube is obstructed at its proximal end by inability to pass a probe or force air through it, and remove the obstructing portion including the horn of the uterus down to the uterine mucous membrane, taking care not to involve the vessels immediately below the fallopian tube. Split the proximal end of the remaining portion of the tube about half an inch. Pass a mattress suture through the uterine wall from the serous to the edge of the mucous surface, continue it through the one-half of the split proximal end of the tube from serous to mucous surface and then back from mucous to serous surface of the uterine wall. Deal in a similar way with the other half of the split end from the opposite surface of the uterine wall. Traction is now to be made on these two mattress sutures and the fallopian tube is thus drawn into the wound in the uterus, its mucous membrane becoming continuous with that of the uterus, and its serous surface coming in contact with the raw tissue on each side. The sutures are then tied. Pass two or three interrupted sutures above and internal to the tube to close the uterine wall, taking care not to constrict the tube. The stitch next the tube must grasp its outer coats, so as to secure more firmly its position. All the sutures are made with chromicized catgut No. 0. This insures patency and fixation of the tube. For salpingostomy determine if the tube is obstructed by inability to pass a probe or force air. Remove the obstruction together with the distal end of the tube diagonally across the tube from above downward and outward leaving a projecting mucous membrane and as large an opening as possible. On the superior surface of the tube pass a suture through the serosa a short distance from its free edge and continue it through the mucous coat close to the edge. Pass a similar suture on the inferior and lateral surfaces sufficient to ensure a perfect union of the mucous surface. A probe can now be passed through the opening into the tube and uterine cavity. Thorough asepsis, of course, must be secured. Vaginal section is not suitable for this method; it is necessary to enter the abdominal cavity suprapubically. Several cases are reported.

2. **Cancer of the Prostate.**—Green has thoroughly studied the literature of this subject and is inclined to think it probable

that cancer occurs in as high as from 5 to 10 per cent. of old men suffering from prostatic disease. The frequency and rapidity of the glandular infection have been generally noticed by others. The average age is over 50 years and in one series as high as 68 years. In the majority of cases symptoms pointing toward trouble with the prostate existed for some time before the cancer developed. Cachexia is of similar value; often it appears comparatively suddenly in old prostatics without reason to account for it. Pain is almost an invariable accompaniment. It may be referred to the prostate, rectum, back or other parts. Hemorrhage is frequent, but not so much so as pain. It occurs perhaps in 50 per cent. of cases. The amount of residual urine is of no particular diagnostic value. The prognosis is always grave, though cases have occurred where operation has caused great improvement. He reports cases in which there has been no recurrence for over a year. He says as regards preventive treatment that if gonorrhea can be avoided, the chances for cancer will become much less frequent. In the majority of cases metastasis has already taken place and the system become infected before cancer is diagnosed. The operative treatment can then be only palliative. The chances of recognizing the condition early enough to operate before metastasis gives the only hope for cure. Quite a complete bibliography is attached.

9 *The Non-medicinal Treatment of Constipation. Samuel G. Gant.
10 *The Frequency Wave of Epileptic Seizures. William P. Spratling.

6.—See abstract in THE JOURNAL, xl, p. 1670.

7. **The X-Rays.**—Tousey gives a description of the apparatus and technic in use for the *x*-rays and Finsen rays in ordinary office practice using the commercial current. The cost of such a current is very small, not more than five to ten cents an hour for the *x*-rays and vacuum tube work, and next to nothing for galvanic and faradic work. The apparatus is alawys in working order and has great advantages over the static machine.

8. **Retroversion and Retroflexion of the Uterus.**—The anatomic conditions and cause of these abnormalities are described by Young as also the treatment. The deductions from his study of the subject are given as follows:

1. Retroversion and retroflexion are never simply malpositions of the fundus, but complex changes in the relation of the whole uterus to the other structures in the pelvis and to the pelvic wall.
2. The uterosacral ligaments are the only suspensory ligaments of the uterus when the patient stands, and are the only ligaments not affected by gestation or parturition.
3. The uterosacral ligaments suspend the uterus by their attachment to the lower segment and act as a swing in supporting the rectum. Factors causing the yielding of these ligaments are: Injuries to pelvic diaphragm; increased intra-abdominal pressure; constipation; straining at stool; injuries to the rectovaginal septum, causing retraction of anus, with rectocele.
4. Any method for the relief of these conditions must consider and relieve all the complicating lesions, not the least of these the pathologic condition of the endometrium.
5. All methods for holding the fundus forward must rely on the integrity of the uterosacral ligaments, together with the fibrous connective tissue of the broad ligaments to suspend the uterus.
6. Non-operative measures are applicable to acute traumatic and replaceable non-complicated cases and depend for their value on relief of pelvic engorgement, the restoration of normal circulation and the return of normal elasticity and tone to the ligaments and muscular structures.
7. The Alexander operation has a limited field of usefulness, and is of value only when there is retroflexion and the other ligaments are strong enough to support the uterus, with proper relief of other complications. It must never be forgotten that traction on the round ligaments tends to lower the plane of the uterus.
8. Ventral suspension, when performed in combination with other procedures, does relieve the malposition and prevents a recurrence of the same. Its dangers, when properly performed, are small if any, in subsequent pregnancies. The advantages of the operation are the ease and rapidity of its performance.
9. Ventral fixation is applicable only when the patient has passed the child-bearing period.
10. The ideal procedure is as follows: Curettage; repair of injuries to the cervix, retrovaginal septum and anterior wall of the vagina. Laparotomy. Sacrosuspension. Bissell operation. The disadvantages are the length of time necessary for the operation and its difficulty of performance in fat subjects.
11. In place of the Bissell operation, a ventral suspension may be substituted. This, I believe, is wise when many adhesions have been broken up and the posterior surface of the uterus is denuded of peritoneal covering or the patient's condition demands haste.
12. In nulliparæ a pessary should be worn for six months to prevent traction on the uterosacral ligaments until they have regained their tone. The action of the pessary is due to the fact that, resting on the superior surface of the symphysis, the lower segment of the uterus is held upward and the strain taken off the uterosacral ligaments. The rectocele, when no lacerations exist, is in this manner lessened.
13. The uterus should be curetted as the first step in any of these operations.
14. The adhesions so frequently found in these cases are of the greatest value to the patient, in that they fulfill a munificent purpose of nature in preventing the condition of complete prolapse during the existence of the malposition.

9. **The Non-Medicinal Treatment of Constipation.**—Gant favors the non-medicinal treatment of constipation, advocates the proper education of the patient, drinking of plenty of water, regularity of habits, condemns enemata, and says that massage intelligently practiced is essential. Electricity has been highly spoken of, but he is not prepared to say that it alone is efficacious. Divulsion of the sphincter may be required in either adults or children when the muscle has become hypertrophied or irritable and there is obstruction. Valvotomy by the method of Martin is occasionally indicated, but requires too many manipulations and instruments, too much time involves considerable danger of hemorrhage, infection and peritonitis besides causing serious confinement and discomfort of the patient. He favors for most cases the technic of the clamp operation; thus inserting his clamp which divides the valves from the fourth to sixth day and is discharged with the feces carrying the section of tissue within its grasp. It has the advantage that it can be painlessly applied in one to five minutes. There is no danger of hemorrhage, infection or complications. No dressings are required. The patient is not subjected to discomfort, need not be restricted as to diet, and in his experience it has been more effective than other procedures as it removes a section of tissue nearly half an inch wide and about an inch long. He illustrates the method showing the insertion of the clamps through the proctoscope, and their application to the Houston valves. In his experience non-medicinal treatment has been far more effective than the medicinal.

10. **Epileptic Seizures.**—Spratling finds that in 1,374 cases at the Craig Colony the approximate frequency of the attacks was weekly or oftener in 775 cases, every two weeks in 173, every three weeks in 61, and every four weeks in 244, every eight weeks in about 42, and every twelve weeks in about 49. It is safe to say, he says, that fully 50 per cent. of all confirmed epileptics have an attack weekly or oftener. A notable decline begins after the first-week period and continues up to the eighth-week period. This increase at the fourth week is due to the fact that serial attacks in many female epileptics group themselves about the time of the menstrual flow. Those in the six months' period, and there are a few that go longer, are classed as occasional epileptics; they scarcely ever show the mental impairment of the ordinary idiopathic cases. He suggests that this wave of epileptic frequency can perhaps be found to have a relationship with more or less rhythmic intoxication of the central nervous system.

14 *The Condition of the Vasomotor Neurone in "Shock." W. T. Porter and W. C. Quinby.
15 *A Hitherto Undescribed Membrane of the Eye and Its Significance. Frederick H. Verhoeff.

11. **Cervical Dislocation.**—Walton refers to his former papers (*Boston Med. and Surg. Jour.*, March 21, 1889, and *Jour. Nerv. and Mental Dis.*, 1889). He remarks that the frequency of the accident is shown by the fact that in addition to the eight cases previously published he has observed at least as many others not deserving of special mention from their peculiarities.

He has made a careful study of the vertebræ which leads him to the conclusion that dorsolateral flexion, combined if necessary with slight rotation (to enable the upper articular process to pass the brim of the lower articular process), would fulfill the requirements of replacing the dislocation, the vertebra being afterward rotated into place as by the old methods. This was first suggested by Dr. Richardson. Of the 7 cases which have come to his knowledge since proposing this method 2 have been replaced in sleep, 3 during etherization and 2 by the operation itself. He reviews the mechanism of the dislocation, calling attention to the fact that the articular processes in the cervical vertebræ are so nearly horizontal that one can readily slip forward over that of the vertebra below and fall into the intervertebral notch without necessarily compressing the cord so as to produce paralytic symptoms. If the left articular process has slipped down into the notch, the head will be tilted to the left, the face being still rotated to the right in case of left dislocation. If the articular process has become caught on the crest of the process below, the head will be tilted to the right as well as rotated to the right. The side on which dislocation has occurred can always be determined by the direction of the rotation; the question whether the articular process has slipped into the notch, which is of secondary importance, can be determined by the tilting of the head. In case bilateral dislocation has occurred, the head will be carried forward and tilted directly backward. The only conditions which are likely to be confused with this cervical dislocation are torticollis and vertebral disease. The former may be determined by contraction of the sternomastoid. In cervical caries the history is the important diagnostic factor. He gives an illustration showing the method of reduction. The patient should be in a sitting posture for the operation. The head should be rocked, but without traction, for traction only lessens the effectiveness of the fulcrum necessary to reduction.

12. **Gunshot Wounds.**—LaGarde describes the conditions which seem to affect the infection in gunshot wounds and shows the result of experimentation made by firing bullets at varying velocities into animals in which the skin had been well rubbed with finely powdered charcoal. The lodgment of the bullet seems to add but little to the susceptibility to infection, and the special lesions from a ball with a certain degree of velocity as it passes through tissues are necessary to augment the susceptibility to infection. These lesions partake of the nature of hematomata. The extent of the hematomata increases with the velocity of the projectile to a marked degree, and the caliber of the ball also has a decided effect. The fissuring extending laterally from the channel track is another important factor, aside from hematomata. Burned areas are much more susceptible to tetanus infection than simple incisions. It is hopeless to disinfect a channel made by a bullet and the wounds treated by simple dressings did best of all, in Müller and Köller's experimental research, while those treated by radical measures, thermocautery, etc., gave evidences of suppuration in every instance.

14. **Shock.**—Porter has experimented as to the production of shock after stimulation of the depressor nerve, and concludes that exhaustion in the vasoconstrictor neurons can not be the essential cause of the symptoms.

15. **A New Membrane of the Eye.**—Verhoeff announces as a result of his studies:

In the pigment layer of the retina there is a fenestrated membrane, identical in structure and staining reactions with the membrana limitans externa.

The rods and cones are not nervous elements, but modified ependymal cells, and are analogous to sensory epithelium.

The limiting membrane of the rosettes of glioma retinæ is a fenestrated membrane, similar in every way to the membrana limitans externa, and the rosettes correspond to the neuro-epithelium of the normal retina.

The structure of the limiting membrane of rosettes explains why they assume their characteristic spherical and spiral-like forms.

"Neuro-epithelioma retinæ" is no more suitable than "glioma retinæ" for the class of tumors to which these terms have been applied.

18 *Timely Operation in Primary Appendicitis. William H. Wathen.
19 The Hypodermatic Use of Adrenalin Chlorid in the Treatment of Asthmatic Attacks. Jesse G. M. Bullowa and David M. Kaplan.

16. **Tuberculosis.**—Trudeau's lecture is the first of a series to be given by the Henry Phipps Institute and describes the history and development of the Adirondack Sanatorium. See editorial last week.

17. **Pyloric Stenosis.**—Moynihan describes the symptoms and morbid anatomy of pyloric stenosis, the child being at birth usually well nourished and of normal weight, but soon after, sometimes the first day and sometimes several weeks later, the patient begins to vomit and no measures such as change of food, etc., suffice to relieve this condition. The vomited matters are very slightly altered from their condition when swallowed and bile is never present. As soon as milk is taken it is ejected with considerable force. The temperature is subnormal, constipation invariable, abdomen collapsed, and the condition rapidly changes for the worse. The morbid anatomy always shows the same condition: an enlarged and thickened stomach, pyloric region altered with funnel-shaped circular thickening. The stomach curiously resembles the dissected-out bladder and prostate. The causation of the condition is obscure. In some cases the use of a nasal tube and washing the stomach relieves, but in a large proportion surgical measures alone will succeed. The operations are Loreta's operation of dilatation, pyloroplasty as advocated by Dent, and gastro-enterostomy. Which of these will be the generally accepted procedure it is impossible to say, but the statistical results up to the end of 1902 show that pyloroplasty had been performed three times, successfully, and in a fourth case, supplemented by gastro-enterostomy, with good results. Gastro-enterostomy, always anterior, was performed 9 times; 5 recoveries, 4 deaths. In one case the death was due to acute obstruction caused by a Murphy button used in anastomosis. Loreta's operation had been performed 9 times with 7 recoveries.

18. **Appendicitis.**—Wathen pleads for early operation. When the diagnosis is made the case should be operated on before further involvement. When the case has gone beyond the primary and timely stage he thinks it would be best to wait until the abscess is walled off in many cases, but not to let the patient go on to another attack. In many cases of inflammatory or purulent condition in the pelvis, he has found appendiceal involvement, but usually no necrosis. He thinks in such cases the appendix should be removed as it adds but little to the danger of any operation and does away with a condition that may cause future trouble.

25 Hay Fever: A Discussion of Our Present Knowledge of the Disease, with Special Reference to Etiology and Therapy. Raymond Wallace.
26 Medical Advancement. William M. Welch.

20. **Liver Abscess.**—Rhoads criticises the use of aspiration in liver abscess on account of its uncertainty, and the danger of withdrawal of the infected end of the needle through the liver tissue. He prefers to diagnose by careful percussion and observation for tender spots, followed by exploratory incision, if required. After the location of the pus he would open and clear out the cavities and use rubber and gauze drainage. The most serious cases are where the thorax has to be opened and one or two ribs resected which is necessary for good drainage. The technic employed is described in full detail and can not well be reproduced. He gives morphin and atropin to relieve pain after the operation, and if much blood has been lost saline transfusion, with the application of dry heat and an enema of hot coffee for shock. Free discharge will necessitate change

of dressings about eight hours after operation. On the following five days the dressing is changed twice a day, the patient being removed on a litter into another room so that the bedding and mattress can be aired. During the first six days, while the fibrous adhesions are forming, the patient is kept mildly under the influence of an opiate; the effects on the nervous system will determine the dosage. On the sixth day adhesions will have formed and the gauze drainage and rubber tube will be surrounded by a fibrous exudate which will have established a pathway for the pus, and they can be removed, therefore, with safety. The cavity is irrigated with warm sterile water until the flow returns clear, and a new rubber tube is carried into the cavity with strips of sterile gauze packed around it down to the abscess cavity. This practice is continued on each successive day until there is no further evidence of pus, and the sinus is allowed to close after the second week. The patient may then be about in a rolling chair in a reclining position and during the last days of local treatment will be walking about if the systemic conditions are favorable. In the convalescent stage, about ten days after operation, the patient is given thrice daily, on an empty stomach, 30 c.c. of pure olive oil in a wine glass into the bottom of which has been squeezed 10 c.c. of lemon juice. The patient soon acquires a taste for it and improves under the treatment. The effect on the intestinal dejection is marked. The oil acts by stimulating the portal circulation, increases the flow of bile, restores a natural digestive agent and antiseptic to the intestinal canal, and heals the ulcers. The dietary must be generous in quantity, but not overwhelm the digestion. He prohibits milk foods, broths, etc., but gives a solid diet in conjunction with the olive oil, administration of minced meats, well-cooked vegetables, salads and shellfish. Whatever foods are ordered, the end in view must be to give the large bowel rest.

21. **Paraffin Prothesis.**—Morton reports a number of cases and illustrates his article with microscopic drawings showing that the paraffin disappears and is replaced by connective tissue and embryonic tissue within four months. The dangers of sepsis, emboli and sloughing are mentioned. Sepsis can be prevented by asepsis; emboli by using the paraffin at the proper temperature though experiments seem to show that paraffin, the melting point of which is below the temperature of the body, gives rise to thrombosis. He doubts whether this is as dangerous as the experiments would lead one to believe. He uses paraffin of a melting point of 109 F., brought to this point by adding sperm oil, and sterilized by placing in a water bath, and exposed to heat sufficient to boil the paraffin.

22. **Tuberculosis in the Negro.**—Coleman analyzes the mortality statistics of Charleston, S.C., Augusta, and Atlanta, Ga., and New Orleans, La., as typical of the South, showing that the ratio of deaths from tuberculosis in the negro is much greater than in the whites, and gives as the reasons their immorality, irregular habits, general lack of hygiene, etc. He thinks with proper measures thoroughly carried out, this mortality could be wonderfully reduced.

24. **Funic Pulsations.**—Good holds that pulsation in the umbilical cord is of fetal and not of maternal origin. To illustrate this he reports an instance where pulsation persisted for some time after the placenta had been expelled from the uterus. The time to ligate the cord, he says, is when there is firm contraction of the uterus.

27 *Personal Experience in the Treatment of Typhoid Fever. J. Franklin Welch.

27. **Typhoid.**—The treatment of typhoid advocated by Welch is proper nursing, plenty of sterile drinking water, a bland, liquid, digestible diet, the use of the Brand method if possible, but sponging in other cases. He thinks medicines have their share in the treatment. It is highly important that the bowels be freely evacuated in the beginning, and for this he would give mild hydrargyrum chlorid and sodium bicarbonate in grain doses every hour followed by carbonate of guaiacol in 3-gr. doses, alternating with the following prescription: Liquor potassi arsenitis, 1 dram; nitrate ammonia, 2 drams; distilled water, 3 ounces, given in teaspoonful doses. These have been very satisfactory in his hands. Guaiacol is a splendid antiseptic, Fowler's solution, an antidote to malaria as well as a good nerve tonic, and the nitrate of ammonia, a mild cardiac stimulant, all of which are indicated in the treatment of typhoid fever in the Mississippi Valley.

32 *Gigantism and Leontiasis Ossea, with Report of the Case of the Giant Wilkins. (Continued.) Peter Bassoe.
33 *Studies on the Cerebral Cortex in the Normal Human Brain and in Dementia Paralytica. (Continued.) G. Alfred Lawrence.

31. **The Orbicularis Sign.**—This sign, which consists in inability of a hemiplegic to voluntarily close the eye on the the generally accepted one of Broadbent, that it is due cussed by Jacoby with reference to its significance in facial paralysis. The theory for the reason why the upper facial is free or less involved in central paralysis accepted by him is the generally accepted one of Broadbent, that it is due to bilateral representation of this innervation in the brain. As regards facial paralysis, the question of decussation arises. He reviews the literature of the subject and reports cases which seem to bear out his ideas, giving his conclusions as follows:

1. The statement of Bard, that the sign is invariably lacking in peripheral facial paralysis and is, therefore, a distinguishing mark of central affection, is incorrect. 2. The presence of the sign in peripheral paralysis is further proof of the existence of commissural fibers between the nuclei of the seventh nerves. 3. The sign is of clinical value, in so far as its presence in peripheral paralysis shows that complete recovery has not yet occurred. 4. The secondary over-action in the orbicularis palpebrarum, which is late in appearance and always coincides with some recovery in power, does not occur in those cases in which the sign, having been present, has passed away.

32. **Gigantism and Leontiasis Ossea.**—Bassoe tabulates the literature of 42 cases. He finds that heredity seems to play no part in the production of this condition, and that the association of sarcoma must be more than a coincidence. The symptoms are explainable by pressure. The diagnosis discussed is between the conditions described and osteitis deformans, acromegaly, sarcoma, etc. There is little to be expected from treatment.

33. **Paresis.**—This installment of Lawrence's article is mainly devoted to technic and an examination of the cortical changes.

39 Congenital Gastric Spasm. J. Park West.

36. **Vulvovaginitis in Hospital Service.**—Koplik notices the tendency of this disorder to spread under hospital conditions and gives illustrations from epidemics sometimes started among the children. It is conveyed, he thinks, in many ways. The utensils may be the first source of infection or the linen and rubber sheets, diapers, underclothing, wash rags and basins and last, but not least, the bath tubs. Every child on admission to his service is thoroughly examined first of all for any rectal, urethral, or vaginal discharge and cultures taken. No child is bathed in the common bathtub until pronounced free from vaginal, rectal or urethral discharge by the house physician. Each child is given an individual basin, comb and bedpan kept at the head of each bed. No bar soap is used; the liquid soap alone. Each bed is fitted permanently with a small brass thermometer case and every patient supplied with his own thermometer, which, with its case, is carefully cleansed

and disinfected after discharging the patient. A bedpan once having been used on a patient suffering from discharge is never again used on a well one. The diapers are made of cheesecloth and thrown away when soiled. In case of patients with an infectious discharge the bed is surrounded by a red bandage to warn the nurses, and the bedding, rubber sheets, draw sheets, and all the linen are marked V. D. (vaginal discharge) and never used again except in a similar case. He has thus instituted a most complete system of isolation protecting each little patient from the others. Should a case be received it can not spread. It is not a simple matter as he has seen deaths occur from infection of the peritoneum resulting from this condition, and many cases of subsequent trouble and sterility in later life can be traced to this infection in early childhood.

41 *Radical Cure for Blennorrhea of the Lachrymal Sac. E. F. Snydacker.
42 Compound Fractures. I. C. Gary.

41. **Lachrymal Blennorrhea.**—Snydacker prefers the subperiosteal operation for this condition, starting the incision above the internal canthal ligament, extending downward 2 or 3 mm. anterior to the crest of the lachrymal bone for a distance of 2½ to 3 cm. The incision extends through the periosteum, which is raised with an elevator down into the lachrymal fossa. In this way the nasal and posterior surface of the lachrymal sac can be lifted up with the periosteum as far as the beginning of the lachrymal canal. The superior portion of the sac can then be separated from its attachment to the surrounding tissue by carefully cutting with small scissors. Then the sac and periosteum are seized with forceps and pulled up so as to cut the sac off as low down and as near the beginning of the canal as possible. The beginning of the canal should be thoroughly curetted so as to make good drainage into the nose. The wound is sutured and a pressure bandage applied. He considers this the easiest and quickest method of performing an operation; better than dissecting out the sac without the periosteum. There is no question in this method of removing the sac entire.

48 Observations in the X-Ray Treatment of Malignant Disease. Finley R. Cook.
49 New Treatment of Cicatrices. Henry R. Varney.
50 *Radiotherapy, with Report of Eleven Cases. Charles D. Center.

43. **X-Ray and Radium for Cancer.**—Morton holds that the earlier the malignant disease is discovered and treated by the *x*-ray the better, and that in its earlier stages radiation treatment is preferable to operation. When cancer has become more advanced operation is required. After operation the *x*-ray treatment is always advisable, and for non-operative cases there can be no question but that it offers the only chance for relief. He points out certain considerations: 1. That treatment should be begun early before the involvement of the lymphatic system to any extent. 2. The type of cancerous diseases is an important consideration. Squamous-celled carcinoma or the rodent ulcer type may claim the possibility of 100 percentage of cures. 3. If the cancer, however, has broken down and become a large open ulcer the chances are less than if the skin remains unbroken. 4. Open ulcers, moreover, offer a chance for secondary septic infection. For this reason he invariably covers the open ulcer during treatment with a layer of absorbent cotton. The intensity of the ray is a matter which severely tests the judgment of the operator. In deep-seated carcinoma of the breast or other internal tumors there is no doubt that treatment can be carried to the point of exciting severe dermatitis to the advantage of the patient. On the other hand, in superficial growths or one directly beneath and involving the skin, there is great danger in producing dermatitis. In such cases the operator may either kill or cure the patient. Gentle *x*-ray treatment given three times weekly to the point where reddening of the skin is not pronounced, will often cause these tumors to shrink and wither away, while severe *x*-ray treatment would produce rapid extension of the disease. Morton alludes to the publication of Edison in regard to cancers and the notion that the system may become saturated with the *x*-ray and subject to a multitude of ills. He says it is hardly fair to compare the intelligent use of the agent to the protracted exposures of the hands and arms of exhibitors, and the bugaboo of over-saturation by the *x*-ray does not exist in scientific medicine. His method is to give treatments three or four times a week, of fifteen to twenty minutes' exposure at a distance of 9 in., with *x*-ray radiation intensity affording a given picture of the lower end of the radius and ulna at 2 feet; thus producing a fair dermatitis in two to four weeks. By following this plan he has never been surprised with an unexpected burn of any severity. In cases where the treatment must be general, as in Hodgkin's disease, the patient may be exposed to the rays at the distance named and the intensity referred to daily for three-quarters to an hour without suffering harm. He does not believe in shields for the local treatment of cancer. The greater the area treated the greater the chances of safety to the patient. His theory of artificial fluorescence of living tissues is mentioned and he remarks on the use of radium, which he says has much the same effects as the *x*-rays. He describes his technic.

44. **Lupus Erythematosus.**—Gottheil believes in the treatment of lupus erythematosus by the Finsen light rather than by the *x*-rays, and remarks that it differs markedly from the latter. In the latter the reaction is uncertain and may appear late and be deep-seated. In the light treatment the reaction is superficial and appears quickly, lasting only a short time and never does any harm. His results he claims are brilliant, though one of the cases he reports was a failure. It was a case of long standing and very extensive disease.

45. **X-Ray Work.**—From his experience with the *x*-rays Edwards concludes that there is no place in the work for empiricism and no one should undertake it without being reasonably familiar with the physical, physiologic and therapeutic properties of the agent. It is a comprehensive and difficult branch of therapeutics and should be taught in medical schools. While in competent hands it is safe and reliable and capable of great good, in incompetent ones it is an agent fraught with great mischief. In the hands of the experienced operator with improved apparatus and technic he holds that 100 per cent. of skin cancers may be cured. Lesions involving the mucous surfaces about the head are more difficult to control and until improved methods are devised for working the rays on unexposed regions in the mouth and throat, not over 50 per cent. of cures can be expected. Lesions involving the cervix uteri and other accessible parts should be controlled by an intelligent, persevering fight. Deep-seated subcutaneous growths, adenomas, etc., should be controlled before dissemination. In all cases relief from pain and other sensory disturbances, retardation of the progress of the disease and general improvement may be expected. In accessible lupus vulgaris a cure may be anticipated in every case. Lupus erythematosus is difficult and requires more radical and severe treatment than is ordinarily demanded.

53 A Case of Syphilis of the Peripheral Nerves and Lungs. Charles M. Remsen.
54 The Medicine and Doctors of Juvenal. Eugene F. Cordell.

52. **Status Lymphaticus.**—The following are the conclusions of Blumer's article:

1. The condition known as the status lymphaticus is a definite pathologic entity. 2. It is probably associated with, if not due to, a condition of intermittent lymphotoxemia. 3. It may be associated with sudden death, probably as a result of lymphotoxemia alone in some cases, or as a result of the action of toxic, physical or psychic injuries, which are rendered much more powerful than usual by the predisposing action of the lymphotoxemia. 4. In some cases the sudden death is undoubtedly mechanical and due to asphyxia from pressure of the enlarged thymus on the trachea. 5. The subjects of the status lymphaticus can be recognized clinically in some instances.

56 *But One Profession of Medicine. Dudley S. Reynolds.
57 *Pertussis. Philip F. Barbour.
58 *A Plea for More Accurate Diagnosis in Diseases of the Upper Abdomen. Louis Frank.

56.—This article appeared in THE JOURNAL, xl, p. 1781.

57. **Pertussis.**—The dangers of pertussis are pointed out by Barbour. The treatment which he considers most useful is that by calcium sulphid. It has proved more efficient than any other agent in his experience. It is not always possible, however, to obtain it in an effective condition, as most calcium sulphid on the market is inert, he says, because it is not sufficiently protected from oxidation during its manufacture, or it deteriorates from imperfect protection afterward. The chocolate-coated pills, he thinks, retain the salt in a purer condition than the gelatin coated. The dosage is approximately ½ gr. every two hours for a child 1 year old, but it may be used in larger or smaller doses according to the results. The object is to saturate the system so that the breath smells of hydrogen sulphid. At the orphan asylum of which he is in charge 15 cases occurred rather consecutively during 1902. In two months after the beginning of the epidemic the last child affected was entirely well of the cough which follows the convulsive stage. When we consider that the average case of whooping cough lasts three months under the most favorable conditions this result would seem to be remarkable.

58. **Abdominal Diseases.**—Frank holds that chronic indigestion and dyspepsia *per se* do not exist in nearly the number of cases so diagnosed, and that disorders which give rise to the symptoms are generally those of the gall bladder or due to stomach ulcer. Only careful examination and gastric analysis can reveal the true state of things, and early diagnosis is better as giving the patient more chance. If a strong presumptive diagnosis can not be made from the symptoms by exclusion an exploratory operation is advised.

59 *Operation of Total Extirpation of the Prostate in Its Capsule. J. B. Kennedy.
60 *Conclusions from Fifty-one Intubated Fatal Cases of Laryngeal Diphtheria. B. R. Shurly.
61 A Case of Gunshot Wound of the Brain. Hal C. Wyman.

59. **Prostatectomy.**—Freyer's operation of perineal prostatectomy is advocated by Kennedy, who describes the method which, as is well known, is preceded by suprapubic cystotomy. He has himself employed it in a number of cases similar to those in which he has seen Freyer operate and with the best results. Five of them are reported.

60. **Laryngeal Diphtheria.**—The 51 cases here analyzed by Shurly point out the importance of the early administration of large doses of antitoxin and immunization of those exposed. He calls attention to the fact that there is a misunderstanding among physicians as to the meaning of double x and single x serum, which are simply measures of quantity and not of strength of units. In other words, 2,000 units single x are identical in curative value with 2,000 double x, and a mistake may lead to fatal results. The chief reasons why the cases analyzed were fatal he gives as follows: 1. Delay in giving the large initial dose of antitoxin, either by delay in calling the physician or by delay by the physician. 2. Insufficient dosage at later intervals. 3. Delay in intubation. 4. The presence of hypertrophied tonsils and adenoids. 5. Lack of proper nursing. With proper attention to dosage he thinks the mortality will be reduced to at least 5 per cent. and intubation be given its proper place among the rarer methods of operative interference.

Therapeutic Gazette, Detroit.

62 *Hyoscin in the Treatment of Morphinism. George E. Pettey.
63 A Note on the Internal Administration of Adrenalin for Control of Hemorrhage. Homer Dupuy.
64 *Symptoms and Diagnosis of Gastric Ulcer, with Remarks on the Treatment with Large Doses of Subnitrate of Bismuth. John B. Woodville.
65 *Directions for the Use of the Vaginal Douche. Byron Robinson.
66 *Some Reasons Why We Should Use Antiseptics in the Treatment of Typhoid Fever. J. M. Peck.
67 Treatment of Menière's Disease, with Report of Case. J. M. Bradley.

62. **Morphinism.**—Pettey answers Crothers' criticism as to the use of hyoscin in the treatment of morphinism, claiming that while it does not cure morphinism, and any one who expects it so to do will be disappointed, it fills a most important place in the treatment. It controls suffering from the withdrawal of morphin, and when used in the quantity and for the length of time it is required for that purpose may be used with absolute safety. Although it is a narcotic, it differs so greatly from morphin in its effects that its use for the length of time required does not perpetuate the desire or necessity for the use of morphin. It overcomes both of these and keeps the patient comfortable while he is abstaining. He does not see what more can be expected.

64. **Gastric Ulcer.**—Woodville treats gastric ulcer by diet restricted to sweet milk with the white of one or two eggs beaten up in half a glass of water at intervals of two to three hours, and the use of subnitrate of bismuth in doses of 45 to 120 grains, suspended in half a glass of milk, three times a day, continued without intermission for three weeks. Used in this way bismuth relieves the vomiting and forms a protecting coat over the ulcer under which the process of repair may go on without interruption. Usually at the end of the time mentioned the diet can be increased by the addition of broths, soft-boiled eggs and crackers. He reports cases. He has never seen any cases of poisoning by these large doses of bismuth. He keeps the bowels open by daily rectal injections and never gives cathartics to the patients by the mouth.

65. **The Vaginal Douche.**—Robinson uses for this purpose a fountain syringe with a four-foot head. He begins with four quarts to those accustomed to it, and two quarts to those who are unaccustomed, at a temperature of 105 F., increasing both the amount and the temperature until the water is as hot as it can be borne, and until a maximum of fourteen quarts is used. He gives the douches in the morning and in the evening just before retiring. The duration required to take each gallon of douche is eight to ten minutes, though less if the full amount is given. The patient should be on the back with thighs and legs flexed. A handful of salt or a teaspoonful of alum can be added to each gallon to dissolve the mucus and pus, acting also as an astringent and antiseptic and for hardening the tissues. Other astringents are less valuable. Sodium sulphate is the best general solvent for the discharges. The tube should be sterilized, boiled and each patient should have her own. The utility of the douche is that it contracts the tissues and vessels, absorbs exudates, checks secretions, stimulates, relieves pain, cleanses, checks hemorrhage, curtails inflammation and drains the genital tract. The best disinfectants for the douches are carbolic acid, permanganate of potassium and biniodid of mercury. Disinfectants, however, are secondary in value to solvents of mucus, pus and leucocytes. The douche should be non-irritating, should be clear, economical and to be of curative effect in pelvic disease should be continued for months.

66. **Typhoid Fever.**—The wisest course in typhoid, according to Peck, is to treat the cases under the assumption that there is sepsis in the intestines. Of the numerous antiseptic agents which may be administered there are none, he thinks, so good as chlorin and acetozone. His first experience with chlorin was in 1895. Since then he has never attempted to treat a case without its use. As yet he has had no experience with acetozone, but numerous testimonies lead him to class it with chlorin. Neither of these drugs are injurious to the human organism, but promptly kill typhoid bacilli in the presence of moisture outside of the body, and when given early in liberal

quantities to persons infected with typhoid bacilli the majority of the characteristics of severe typhoid do not appear. He mentions also urotropin for clearing the urine as another valuable antiseptic; also sulphocarbolate of zinc, guaiacol, mercury and salol, but all as secondary to chlorin and acetozone.

69 *The Fatality of Whooping Cough. Eliza H. Root.

69. **Whooping Cough.**—The fatality of whooping cough which is popularly considered to be almost *nil* is pointed out by Root as a decidedly serious matter. She says that statistics prove that it is more fatal in many localities and at certain times than scarlet fever. In the United States Census Report for 1900, for example, we find that 663 died in New York of whooping cough and 549 from scarlet fever. Death usually occurs from the complication of pneumonia, but asphyxia or marasmus, cerebral apoplexy and emphysema after rupture of the larynx are occasionally reported as the cause of death. Severe disturbance of the nervous system or intelligence, visual defects or even deaf-mutism may remain after apparent recovery. While whooping cough is not carried by individuals not ill of the disease, it is actively contagious from one person to another. Its control need not be so complicated and far-reaching as that of scarlet fever. It is advisable, however, that it should be isolated. To make it a notifiable disease would add in gathering statistics and give us better data as to its true serious import.

12 *The Open-air Treatment of Surgical Tuberculosis. Edward Deanesly.

3. **Tuberculosis of the Uterus and Adnexa.**—Targett shows the frequency of this complication in the statistics of the Brompton Hospital, Johns Hopkins Hospital and elsewhere. In many cases tuberculosis is not diagnosed and the naked eye changes are often so slight as to be overlooked. The fallopian tubes are the points of attack in nearly 90 per cent. of cases; and in them it may take on one of three forms: diffuse miliary tuberculous salpingitis, caseous tuberculous salpingitis and tuberculous pyosalpinx. The peculiar features of tuberculous pyosalpinx are its elongated banana-like shape, the persistence of the fimbriated extremity, the absence of adhesions on its serous surface, and the comparative thinness of the sac wall. The contents are usually free from pyogenic organisms and often do not contain tubercle bacilli. The uterine extremity will, however, be found thickened and have the characteristic structure of tuberculous growths. Tuberculosis of the body of the uterus he finds remarkably similar to the condition in the tube. We have thus a caseous tuberculous perimetritis, a diffuse miliary form, less frequent, and the true pyometrium, comparable to the pyosalpinx above described. In the majority of cases the uterus is infected by extension of the disease from the tubes, rarely from the cervix. He considers primary corporeal tuberculosis dubious, though it has been attributed to placental infection. As regards diagnosis he insists on the importance of previous history and the absence of other causes. Pregnancy seems to favor the development of tuberculous peritonitis. There is comparatively little disturbance in the menstrual function; menorrhagia is not so common as in other forms of chronic salpingitis. Dysmenorrhea is certainly a common symptom in tuberculous salpingitis, but the absence of pelvic pain is considered worthy of note. Some writers have laid great stress on the nodular feel of the diseased tubes, such nodules often being in close relation to the uterus and may justify the suspicion of tubercle, though we would have to exclude malignant disease. Lastly, when the disease is affecting the uterine cavity it may be possible to detect the tubercle bacilli in the discharges or discover the structure of tubercle on microscopic examination of the uterine curettings. Whether or not it is wise to attempt removal of caseous tubes when surrounded by dense adhesions further experience must decide, but there is no doubt that tuberculous pyosalpinx can be best treated by abdominal resection. The dangers of laparotomy are adhesions of the bowel to the abdominal wall, the density of the fibrous adhesions around the appendages, the rottenness of the bowel and tissues generally and the risk of fecal fistula. When the uterus is affected its tissues are easily torn and dilating and curetting may cause serious ruptures.

Kynoch describes primary tuberculosis of the cervix, recognizing the ulcerative form of miliary tuberculosis representing the early stage of ulceration and the papillar form involving the cervix endometrium and extending into the vaginal process, red and bleeding, soft and non-friable, and in these respects differing from epithelioma. He reports a case and remarks that such localized tuberculosis is more frequent than is generally supposed. The symptoms are not satisfactory for diagnosis. In the absence of tuberculosis elsewhere with the surrounding parts apparently healthy, hysterectomy is the best treatment. Palliative treatment should be reserved for cases that are obviously secondary to active tuberculous lesions elsewhere.

5. **Prostatectomy.**—Freyer continues his article, reporting additional cases. Of the 51 completed cases, 46 have been perfect successes, the patients continuing to be well. There has been no permanent fistula, contraction at the site of operation, stricture or dangerous hemorrhage during or after operation and no case of septicemia, which is remarkable, considering that the bladder was septic before operation. He suggests that persons that survive to a condition in which these cases are when operated on, become more or less immune by the gradual absorption of toxins and thus do not become septic. There were 5 deaths out of the 51 cases; 2 from mania after the wound had healed and the urine was being passed naturally; 1 from heat stroke during convalescence, 1 from coma from retention of morbid products which had set in before the operation and 1 from pneumonia seven days after operating. In only one of the cases could the fatal results be attributed to the operation. In his last 19 completed cases there has been no such accident. He remarks on the frequency of mental disorder among persons suffering from prostatic disease and says that more than ordinary risk is attached to an operation of any kind in such cases from its being likely to accentuate the mental symptoms.

6. **Erb-Duchenne Paralysis.**—Tubby has attempted to relieve this condition by splicing the muscles, attaching the triceps to the biceps and thus enabling flexion of the arm to be secured. The replacement of the paralyzed deltoid is more difficult, but he has used for this purpose the clavicular portion of the pectoralis major and that part of the trapezius attached to the clavicle. These cases promise better results. An important point after muscle-grafting operations of any kind is that the grafted muscle must never be put on the stretch for at least a month, and then it must still be kept under control, and very gradually be allowed to attempt to perform its full function.

8. **Club-Foot.**—Phelps' operation for club-foot, which was severely criticised when presented before the British Medical Association in 1900, is strongly advocated by Little. He varies it slightly by dividing the tendo Achilles last and using a skin flap which has also been employed for this purpose by Jonas of Omaha. He does not put the foot in gypsum immediately after operation as oozing occurs and a bulky dressing is required which prevents a good hold on the foot being obtained, and also because blood-stained dressings are likely to be irritating. He illustrates his paper, showing his results. He has never had serious trouble from scar and if the skin flap is employed this is avoided. He is convinced that there is no ground for fearing recontraction or relapses. The chief danger, he thinks, is in the production of flat-foot. To secure good results it is absolutely necessary to keep the fore part of the foot fully abducted and the inner border stretched from the time of operation until the wounds are soundly healed. His conclusions are:

1. In selected cases Phelps' operation is of great value. A skin flap should always be made. 2. Osteotomy as a part of the operation is rarely necessary. 3. The operation is contraindicated in young children because of the difficulty of predicting what the ultimate result of growth and pressure may be and the danger of severe flat-foot following. 4. If, for reasons of expediency, cases must be operated on young, and flat-foot result, the patient is far better off than if he had a relapsed or partly curved varus.

9. **Cystic Tumors of the Mammae.**—Snow holds that many of these cystic tumors are simply milk engorgements which

can be milked out by forcible massage and thus do away with the necessity of operation.

11. **Gastric Ulcer.**—Moullin advocates operation in chronic gastric ulcer and in every possible case he favors dealing with the ulcer directly in preference to gastrojejunostomy. Posterior gastrojejunostomy, especially with lateral anastomosis between the two sides of the intestinal loop, is, however, an excellent operation. If the ulcer is multiple; near the pylorus or cardia or if it is too large or deep, or if it has contracted such dense adhesions that removal is impracticable, gastrojejunostomy may be the only resource. The ideal method is excision. The success depends on whether the operation is a preventive against future trouble or used as a last resort. Of the former class he has had 23 cases, with but 1 death, and of the latter, 15 with 5 deaths. Two of these fatal cases were almost moribund at the time of operating, and the others were more or less hopeless.

12. **Surgical Tuberculosis.**—Deanesly advocates the open-air treatment for surgical tuberculosis and claims that every hospital should be provided with facilities for treating patients in the open air.

21 *On the Etiology of Bubonic Plague: An Epidemiologic Contribution. J. Ashburton Thompson.

17. **Sciatica.**—The Weir Mitchell treatment by rest and a long splint is advocated by Clarke, who has found it successful in the severer cases of sciatica that have come under his care. Out of the last 12 consecutive cases of severe sciatica 10 patients were cured, 1 had a relapse but was cured by a second course of treatment. One could have been relieved, but he was restless and impatient and it was impossible to keep the splint on. The restraint of the splint is rather inconvenient for the first day or two, but later is more endurable. Gastric affections must be looked after by careful feeding and a light diet is better in all cases at first. Care must be taken that the bed is flat and even and that there is a firm basis of support under a flat mattress. The limb must be absolutely at rest; this is essential to treatment. A short course of massage, tonics and cod-liver oil is an aid to complete cure.

21. **Bubonic Plague.**—Thompson finds from experience with plague at Sydney, Brisbane and Port Elizabeth that the transmission of plague must be through the skin and that the best carrier that meets all the requirements is the flea. The objections to this theory are reviewed and answered. He admits that infection by occasional contact is possible, but says that the chances against it are so many that it can not be relied on as a cause of an epidemic.

28 Notes on Three Cases of Scirrhus of the Breast. Robert Scott.
29 *Short Notes on the Radical Cure of Umbilical Hernia. C. E. Todd.

25. **Appendicitis.**—Hinder advocates operation and thinks recovery from general peritonitis depends on the rapidity with which patients are submitted to operation. He agrees with the theory that appendicitis is usually caused by interruption of the outflow of the mucous secretion of the organ and that this interruption is caused primarily by a congenital narrowing near the cecal end of the appendix. This becomes a complete blockage from causes arising within or without the organ, for example, a concretion thus produced causes inflammation which effectually closes the already narrow outlet.

29. **Umbilical Hernia.**—Todd emphasizes the importance of not opening the hernial sac from the outside if it can be avoided; also that an abdominal incision should be made well away from the bulging; whether above it or to one side matters very little. The first incision should be long to give room to examine the structures. He says that operation in the early stages would save many fat and elderly women much trouble.

41 Phlycténose récidivante des extrémités. E. Bodin. One case.

37. **Histopathogenesis of Psoriasis.**—Verrotti's article is a presentation of arguments in favor of the conception that psoriasis commences primarily as a congestion, involving the entire derma. It assumes later the character of an inflammation in the papillary and subpapillary layers, causing a series of changes in the rete mucosum by the degeneration of the vacuoles and reactive proliferation, the resulting product of which is parakeratosis. He proclaims that the conception of a toxemia as presiding over the production of the cutaneous lesions in psoriasis is justified by the nature and the evolution of the histologic changes.

38. **Histology of Chronic Circumscribed Lichen.**—Dalous describes 2 cases very carefully studied and announces his opinion that this affection may be defined as a peripheral neuritis of central origin.

39. **Subcutaneous Abscesses of Mycotic Origin.**—The patient was a man of 37 who exhibited thirty-five small tumors irregularly distributed over his body and head, the face exempt. The tumors were only slightly painful under palpation and in appearance suggested hydatid cysts, but each contained pus resembling that of tubercular lesions. A mould fungus was derived from the abscesses, which did not prove pathogenic for animals, but autoinoculation from the abscesses reproduced them on the subject. Energetic treatment with potassium iodid was followed by the complete retrogression of all the tumors in about six weeks.

43 *De la tuberculose articulaire et abarticulaire et des séries morbides parallèles. C. Fernet.

43. **Tuberculosis of the Joints.**—Fernet's experience has confirmed that of others in regard to the manifestations of tuberculosis in the joints. They may assume an acute or chronic form, and they resemble in many respects those of articular rheumatism. They have been called, therefore, tuberculous rheumatism, tuberculous-pseudo-rheumatism, etc., but he protests against these appellations as indicating a relationship to rheumatism which does not exist. It is more correct to say articular tuberculosis just as we say pulmonary tuberculosis. In other words, the tuberculosis may manifest itself in morbid

series which parallel those of acute or chronic rheumatism in their localization in the joints or elsewhere. But the lesions have nothing in common except their site. They differ in causation, pathologic anatomy and in their symptoms. They should, therefore, be differentiated and entitled differently.

49 Appendicocèle extra-péritonéale et appendicite herniaire extra-péritonéale. F. Guibal and E. Roland. One case and review of 7 in the literature.

44. Chloridemia and Treatment of Bright's Disease by Dechloridation.—The details of careful study of 6 patients treated by dechloridation are given and one case is tabulated with all the particulars. Widal's announcements in regard to the importance of a salt-free diet in nephritis have been reviewed in these columns as published with editorial comment last week. He proclaims that it is absolutely necessary to know the variations in the "salt equilibrium" in a nephritic patient before treatment can be intelligently instituted. He measured the amount of salt ingested and eliminated, keeping close watch of the weight of the patient. By this means it is possible to note the onset of what he calls the pre-edema period. When the results of these tests showed that the kidney was impermeable for salt, then he administered various diuretics, allowing several days to each period and to the intervals. He found digitalis incapable of inducing diuresis when the renal lesion is not complicated by cardio-vascular troubles. The edema in Bright's disease is not produced, like cardiac edema, by insufficiency of the vascular apparatus, but merely by the lack of permeability on the part of the kidney to sodium chlorid. Theobromin is the heroic remedy for this condition; it opens the sluices of the kidney and by re-establishing the outward flow of the chlorids frees the organism of the chlorids which have been retained in it, and eliminates with them the retained water in the saving polyuria. No other diuretic can be compared with it, and its efficacy in pure Bright's disease confirms the assumption that the cause of the retention of fluids causing the edema lies in the kidneys. Sodium chlorid is probably not the only substance arrested by the diseased kidney, but it is the one whose retention is the cause of the chief troubles. As it accumulates in the tissues it raises the index of the concentration of their juices, and this in turn attracts the water to restore the balance. As salt is thus responsible for the disturbances its intake must be restricted. Many persons with Bright's disease improve and thrive on a mixed diet containing meat, bread, sugar, potato and butter so long as no salt is given with them. Milk contains too much salt for large quantities to be advisable in severe cases. Clinical experience is confirming more and more the value of this method of dechloridation when the impermeability of the kidney for salt has been determined by the alimentary salt test or otherwise. It is usually sufficient alone to free the patients from edema, but may be supplemented by use of theobromin or theocin when more rapid action is desired. They owe their efficacy to their power of rendering the kidney permeable to salt. As the salt is eliminated the water retained to hold it in solution escapes with it.

45. Experimental Solar Syndrome.—Lavastine remarks that we can detect a "solar note" in certain perturbations of the visceral functions. He has reproduced them experimentally and shows that an organic lesion is not necessary—a mere perversion in the solar regulating mechanism is sufficient to throw one or more of the viscera out of gear. Insufficiency of the liver may be due to this cause, as well as some of the symptoms noted in lead poisoning, peritonitis, etc. A number of affections hitherto classified by their pathologic anatomy are in reality merely manifestations of derangement of the solar plexus. The syndrome of acute solar paralysis is realized in peritonitis; the syndrome of acute solar irritation is seen in lead poisoning; the subacute and chronic forms of irritation are seen in lead poisoning entailing paralysis of the solar plexus, and also in muco-membranous colitis in nervously irritable subjects. The fourth form of solar pathology he calls the syndrome due to irradiation: death may follow a blow on the abdomen, or ingestion of ice affecting the stomach like a traumatism, and arrest of the heart in diastole observed in liver or kidney colic is due to this cause. Potain witnessed a case in which the pulse was slowed by the influence of the solar plexus. The possibility of a solar factor should, therefore, be thought of in certain syndromes involving the viscera.

46. Syphilitic Icterus.—Simionescu ascribes to syphilis every case of icterus observed in a syphilitic subject presenting secondary manifestations—unless there is proof to the contrary. All syphilitics do not present the symptoms of icterus, as individual predispositions differ. He describes 4 cases. The icterus subsided under specific treatment.

Semaine Médicale, Paris.

51 *Diagnostic Sign of Twin Pregnancy. I. Levinovitch.—Un signe susceptible de faciliter le diagnostic de la grossesse gémellaire.
52 Letters from America. F. Munch.—Sur la désinfection chirurgicale, and La chloroformisation et l'éthérisation aux Etats-Unis.

51. Sign of Twin Pregnancy.—In a normal pregnancy the uterus develops retaining its spherical outline, but in case of twin gestation the tendency is to develop more laterally. The fetuses are usually arranged side by side and the distension in the transverse diameter reduces the traction on the round ligaments until they become much shorter and looser. These ligaments share in the general hypertrophy of the uterus during a pregnancy and they can be readily palpated in a normal gestation. The determination of these ligaments by palpation as a round, prominent ligament under considerable tension, excludes the idea of a twin gestation.

Revue de Gynécologie, Paris.

55 Actinomycose de l'appendice vermiforme. M. Letulle.

53. The Blood in Case of Ovarian Cysts.—Bender gives the blood findings in 23 cases of various kinds of ovarian cysts and proclaims that it is possible to determine the benign or malignant character of the cyst by examination of the blood. The neoplasm is certainly non-malignant if the whites do not number more than 6,000 to 8,000. When the proportion of reds is normal, the presumption is against malignancy even in case of considerable leucocytosis. Only when the reds are below normal and the whites materially increased, are we justified in assuming malignant cancerous degeneration.

58 Sur la lésion dite sténose congénitale de l'aorte dans la region de l'isthme. L. M. Bonnet. (Commenced in No. 2.)

57. The Tonsils and Tuberculosis.—Escomel regards the tonsils as "the most tuberculizable organs in the entire digestive tract." He found them the seat of tuberculous lesions in 21 out of 25 cadavers of consumptives examined. In 11 non-tuberculous cadavers the tonsils were intact. In the tuberculous cases the follicles almost always contained other parasites, which may have favored the lodgment and growth of the tubercle bacilli.

66 The New Gynecologic Clinic at Dresden. G. Leopold.—Zur Eröffnung der neuen k. Frauenklinik in Dresden.
67 *Correction. L. Bossi.—Berichtigung.

59. **Regeneration of Uterine Mucosa After Childbirth.**—Wormser gives a number of illustrations to show the various processes of regeneration. By the end of the third week he found all the elements of the mucosa approximately normal. His monograph of 126 pages reviews 53 other published communications on the subject.

61. **White Infarct in the Placenta.**—These writers argue that the so-called white infarct is rather of the nature of a thrombosis.

62. **Study of Corpus Carcinoma.**—Hitschmann warns that every manifestation of epidermis formation in the mucosa of the uterus deserves attention, even if there is no evidence of tumor formation. He thinks there are no grounds for the assumption of a psoriasis or ichthyosis uterina, but metaplasia of the columnar into pavement epithelium is a frequent accompaniment of adenocarcinoma of the fundus. He reviews his findings in 7 typical cases and in 3 of pure epithelioma, all of the fundus.

67. **Instrumental Dilatation.**—Bossi proclaims that experience is demonstrating that instrumental dilatation is especially indicated for primiparæ and in case of entirely unshortened cervix, when rapid delivery is required in eclampsia, etc.

77 *Operative Treatment of Cancer of Stomach at Krönlein's Clinic, Zurich, Schönholzer.—Chirurgie des Magenkrebses an der K.'schen Klinik von 1881 bis 1902.

70. **Operative Treatment of Invagination of Intestines.**—Hofmeister relates a number of interesting cases from von Bruns' clinic. He advocates resection of the invaginated portion as the standard procedure, and recommends a modification of von Frey's technic. The operation is certain and rapidly done. The afferent intestine is drawn out and divided. The proximal stump is closed with a suture. The peripheral stump is allowed to slide down into the invagination funnel; then follows a lengthwise incision in the invaginatum a few inches below the turned-over part. A ligature is applied as high up as possible, and the inner cylinder is resected, after which the stumps are united by side anastomosis, utilizing the lengthwise incision mentioned above. He gives diagrams to illustrate the technic.

72. **Pneumococcus Peritonitis.**—Brunn analyzes 2 cases personally observed and 56 in children that have been reported in the literature with 15 in adults, and a number of others that lack bacteriologic confirmation. The prognosis is favorable. Spontaneous healing is possible but rare; treatment should consist in evacuation of the abscess by a broad opening with drainage. The diagnosis is based on the fibrinous plastic exudate, which is promptly walled in by adhesions, causing symptoms of acute peritonitis followed soon by a chronic stage with comparatively mild peritonitic symptoms. The pus is a greenish yellow, abounding in fibrin.

73. **Experiences with Posterior Gastroenterostomy.**—Trendel states that only 21.4 per cent. of 28 patients operated on at Tübingen succumbed within four weeks, and only 18.2 per cent. in the 269 cases of the united statistics of Czerny (215), Steinthal (26), and von Bruns (28). No instance of pure stomach ileus was observed. He uses a short loop and the Murphy button. The button was successfully applied in all but 3 cases, but in a fourth it dropped into the stomach and was the cause of fatal after-hemorrhage.

74. **Anatomy and Pathology of Biliary Passages.**—Büngner found that the common bile duct passed through the head of the pancreas in nearly every one of the 58 cadavers examined. In only 5 per cent. did it pass to one side. He also found that this duct and the pancreatic duct open with separate orifices in the floor of the diverticulum of the papilla. All affections which entail enlargement or shriveling of the head of the pancreas must cause constriction not only of the pancreatic duct but also of the common bile duct. An affection of one duct does not necessarily entail involvement of the other.

77. **Surgery of Gastric Cancer at Zurich.**—Of the 264 cases observed, 67 were not operated on; in 73 an exploratory laparotomy was alone attempted; 74 were treated by gastroenterostomy and 50 by resection. Of the inoperable cases 51 lived on an average 73 days afterward. The 14 patients declared operable but who refused surgical intervention, lived an average of 200 days. Heredity was noted in 13 per cent. The mortality of exploratory laparotomy proved to be 9.5 per cent. The mortality in the 74 cases in which gastro-enterostomy was done was 24.3 per cent. It is indicated, Krönlein believes, in cases of inoperable carcinoma of the pylorus with actual stenosis. The retrocolic method shows a mortality of only 16 per cent., and hence seems to be preferable to the Wölfler operation. He uses brief ether narcosis for the cutaneous incision, completing the operation without further anesthesia. The gastro-enterostomy prolonged life on an average for 100 days. In 17 cases the patients were relieved to such an extent that life was prolonged for an average of 410 days. In 17 others the average survival was for 141 days, and in 21 for 64 days. The details of the 74 cases of gastro-enterostomy are related, filling 112 pages. In 56 of the 74 cases the stomach had never given trouble. In 3 there had been a preceding ulcer, and in 7 there had been no vomiting. The first symptoms appeared on an average nine months before the operation; in 9 cases only three or four months had elapsed. The most important diagnostic sign is the emaciation. It was constant, and frequently the first symptom that brought the subjects to the physician, when no other symptoms were apparent except possibly loss of appetite and eructations after meals. The patients in many instances had never thought of their stomach in connection with the emaciation and neither did the physician, but instituted treatment of the assumed anemia, etc. The facts observed emphasize the importance of systematic weighings, and the loss of much important information by the usual neglect of this. Symptoms of any stomach trouble, no matter how apparently benign, if accompanied by emaciation, should suggest the possibility of cancer, and exploratory laparotomy is indicated. The progress of the emaciation is also an important sign. If the subject with a stomach affection loses thirty pounds in a few days the trouble is probably a benign stenosis of the pylorus, while the same loss of weight occurring in the course of six months is presumptive of cancer. In 60 of the 74 cases the gastric secretions were tested and no free hydrochloric acid could be detected in 54, while it was present in the rest, and all exhibited motor insufficiency. In one a cherry stone was found in rinsing the stomach that must have sojourned there for two months. Krönlein's experience confirms the view that cases of carcinoma of the pylorus in which extirpation is impossible, are the most satisfactory subjects for gastro-enterostomy.

79. **Antidiphtheria Serum.**—Weiland's article was prepared as a thesis. He ranks the local inhibiting influence of the serum far above its antitoxic action. His experience confirms that of others that serum treatment has more chances of success in the more gradual, protracted cases than in those with tempestuous rapid course.

80. **Paroxysmal Hemoglobinuria.**—Burckhardt had occasion to study a case of this affection in a six-year-old boy, and became convinced that the attacks were brought on by congestion or chilling in every instance. The blood serum did not seem to possess a hemolytic action outside of these attacks.

85 *Functional Capacity of Mammary Glands and Indications and Contraindications for Breast Nursing. A. Schlossmann (Dresden).—Ueber die Leistungsfähigkeit der weiblichen Milchdrüsen und über Indikationen und Kontraindikationen zum Stillen.

82. **Advantages of the Oblique Arc Incision.**—Menge has opened the abdomen by Pfannensteil's technic in 62 operations and ascribes certain advantages to it over the ordinary vertical incision. If the wound heals by primary intention there is no danger of hernia, but it is liable in case of suppuration. His patients made a smooth recovery in all but 4 cases. The scar is almost imperceptible or is hidden by the hair, and the elastic strain of the abdominal muscles keeps it linear. There does not seem to be the slightest tendency to callus formation or pigmentation at this point. He uses dry asepsis and cumolized catgut, and thinks this incision is preferable for many operations on the internal genitalia in which the uterus is to be retained.

83. **Mechanism of Rupture of Uterus.**—Knauer has recently observed a case in which a bunch of caseous lymph glands prevented the passage of the fetal head into the pelvis. This entailed such distension of the lower segment of the uterus that it ruptured. A hematoma developed, causing in turn such distension of the peritoneum that this also ruptured. The patient succumbed to subsequent peritonitis. In 3 other cases in which the placenta was prematurely detached, the internal hemorrhage caused distension which finally ruptured the uterus wall and peritoneum, the latter in several places. He does not know whether the tissues were previously weakened, but he points out that every case of sudden distension of the uterus with progressive anemia and no external escape of the hemorrhage should suggest the possibility of impending rupture and these fissures in the peritoneum.

84. **Dilatation of Uterus According to Bonnaire.**—Meurer has been well satisfied with the results in 29 cases in which dilatation was accomplished by Bonnaire's technic.

85. **Indications and Counterindications for Breast Nursing.**—Tuberculosis in the mother can scarcely be regarded as a contraindication to nursing her child. The danger of infecting the infant by other means than the milk is far more probable than the danger of transmitting infection in the milk. The tuberculous mother does not seem to suffer from exercise of the mammary function, but a tuberculous wet nurse is out of the question. When tuberculosis is suspected in a wet nurse and the response to tuberculin is negative, several weeks of observation are necessary to fully decide the question. An injection of tuberculin does not affect the mammary secretion nor the nursling. Schlossmann advises leaving the child at the breast during a mastitis if no pus cocci are found in the milk. If the milk contains pus cells the breast should be treated, but the infant can still nurse the sound side. He adds that there are no absolute contraindications to breast nursing, but in individual cases it may sometimes be necessary to decide whether it is best for the mother to nurse her child or not.

90. **Benefit to Health from Fumes of Phosphoric Acid.**—When a person unaccustomed to the fumes of phosphoric acid enters the room in which storage batteries are made, he is almost suffocated. Böttrich has been engaged for fifteen years in supervising the health of the employes in a large factory of this kind at Hagen, examining the men every week. In the making of the storage batteries the employes are apparently exposed to severe irritation of the respiratory organs from the fumes of the acid, and also to the danger of lead poisoning. In all his experience, however, he has never encountered a typical case of lead poisoning among the 45 to 60 men constantly employed at this work, some for as long as ten years. He has also been impressed by the fact that the mucosa of the upper-air passages is unusually sound and resistant. Not a single case of tuberculosis is known among the men and catarrhal affections seem to subside in a remarkably brief time. Several of the men who entered on the work with pulmonary tubercular lesions have regained their health while employed in the storage battery rooms. The general health of the men averages twice as high as that of a similar body of men engaged in a neighboring iron works where railroad supplies are made. He has been so impressed with the salutary effects observed that he suggests the therapeutic application of the fumes of acids used in the preparation of storage batteries. The same conditions could easily be produced elsewhere than in a factory, and he thinks the facts observed justify attempts in this line.

104 *Urobilin in Stomach. A. Braunstein (Ibid.).—Ueber Vorkommen und Entstehung von Urobilin im menschlichen Magen.

94. **Diagnosis of Infarct in Lungs.**—Tiedemann remarks that the pathologic anatomy of infarct in the lungs indicates that if the hemorrhagic infarct is situated near the surface the resonance will be deadened over the spot. Sometimes there is a tympanitic resonance, owing to the vibrations of the air in the bronchi and the relaxation of the adjacent lung tissue. The vocal fremitus is increased except when the infarct is so large as to exert pressure on the chest wall. The infarct was found in the right lower lobe in 15 cases; in the right upper in 7; in left lower lobe in 5; left upper in 4, right median lobe in 2, and once in the left apex. The presence of a cardiac defect or other trouble entailing disturbances in the circulation is an important aid in the diagnosis. Râles may be audible as long as the alveoles are not entirely filled with coagulated blood, but after the infarct has developed, the sounds heard can pro-

ceed only from the pleura above it, from the bronchi or from the surrounding alveolar tissue. While it may be impossible to hear vesicular breathing over the infarct, yet the air-free tissue proves a good conductor for sounds originating in the adjacent bronchi. Circumscribed bronchial-tube breathing may, therefore, be regarded as characteristic. The infarct is usually shaped like a wedge, the broad end toward the pleura, about as large as a walnut or cherry.

95. **Leukemia.**—In one of the 7 cases of leukemia described there were malarial antecedents, in 3 trauma. Four were of the chronic lymphatic type and 2 of the mixed form. In one there was a combination of pernicious anemia with mixed-cell leukemia. In a case of almost pure lymphemia the proportion of lymphocytes to the polynuclear neutrophiles was 99/1. In a case of pseudo-leukemia the lymphocytes were somewhat increased with indicanuria and obstinate profuse sweats, but there were no neutrophiles. Reckzeh also mentions 2 cases of tuberculosis of the lymphatic glands in which the blood was almost normal.

96. **Experimental Lead Colic.**—Mosse found that it was possible to induce cellular alterations in the celiac ganglion similar to what are found in lead colic, by administering drugs which cause violent contraction of the intestines. These lesions in the ganglion are evidently the result of the violent muscular spasms in the intestine caused by the lead.

99. **Subcutaneous Oil Feeding.**—Winternitz administered fats in combination with iodin in subcutaneous injections. The fat thus taken was entirely absorbed and assimilated, but the organism is not capable of taking up more than 20 to 25 calories a day in this way, and months may elapse before a deposit of 500 gm. is entirely absorbed. Not more than 2 to 3 gm. is absorbed during the twenty-four hours even under the most favorable circumstances.

103. **Antistreptococcus Serum.**—Meyer has been testing the various serums of this kind and finds that Aronson's is the only one that absolutely protects animals against several times the otherwise fatal dose, and cures after infection. The intravenous route was found far superior to the subcutaneous and intraperitoneal. The serum from 2 patients who had passed through severe streptococcus infection likewise proved to have protecting power to a certain extent, although very large amounts were necessary. Aronson's serum does not check the growth of streptococci *in vitro* nor attenuate their virulence, but they became very much less virulent when grown in the peritoneum of a protected rabbit. The streptococci probably become attenuated in the body of a protected animal, and thus fall an easy prey to the cells. All the tests showed that the earlier the injection is made after infection the better the results.

104. **Urobilin in Stomach.**—Braunstein's experiments demonstrated that urobilin is not found in the stomach except when the bile entering it already contains urobilinogen. The transformation of the latter into urobilin is promoted by hydrochloric acid. The urobilin in the stomach is thus of enterogenic origin, the same as that in the intestines.

126 Discussion of Prophylaxis of Yellow Fever at Fifth Brazilian Medical Congress.

109. **Treatment of Erysipelas.**—Paes Leme supplements the ordinary internal measures with a local spray of a concentrated ether solution of camphor and a spray of 1 per 1,000 solution of sublimate. The wound which is the starting point for the infection is treated antiseptically and sometimes the patch and the surrounding region are painted with iodin, which he also gives internally.

110. **Treatment of Contusions.**—The same writer applies 15 per cent. mentholized collodion to the contused region to reduce the superficial pain, and dry cupping in contusions of the thorax and shoulders.

112. **Serum Treatment of Plague.**—Ferrari's experience with serum treatment has been extremely favorable. He found that it acted rapidly, without local reaction, and the general reaction was transient and insignificant in most cases. The duration of the disease was much reduced and the reabsorption of the exudate in the infected ganglia was facilitated and hastened. His 56 cases had a mortality of 15.3 per cent., but 2 of the patients were moribund when first seen. The mortality of the severe cases was 22 per cent. and in 6 cases of the most serious form of secondary plague pneumonia only 33 per cent.

113. **Strychnin in Yellow Fever.**—Ferrari has found strychnin very useful in infectious diseases, especially in yellow fever.

114 and 124. **Transmission of Yellow Fever by Mosquitoes.**—The committee appointed to study this subject make a formal report of 3 cases in which men voluntarily allowed themselves to be bitten by mosquitoes previously infected for the tests. Each one of the 3 developed yellow fever after the due period of incubation, and in one it was very severe, in the others light. They regard the tests as completely verifying the experiences of the United States physicians at Havana. Bandi denies the typical character of the disease produced and claims that the tests were inconclusive.

119. **Glucosed Artificial Serum in Treatment of Yellow Fever.**—Guimaraes has only a single case to report but the benefit derived from the injections was so remarkable that he does not wait for further confirmation. The fluid used was a mixture of 200 c.c. of a 1 per 1,000 solution of sodium chlorid and 10 gm. of chemically pure glucose. He injected 10 c.c. at a time and the pulse dropped almost at once from 140 to 116, declining to 100, 96 and 84, while all the other symptoms rapidly subsided. He has treated in the same way a patient with toxemia from gin liver and the benefit was equally marked.

130 *Esophagotomy for Foreign Body. P. I. Kuzmin.—K Kazuistik naruzhnago syetchenlya pishtchevoda pri enorodnykh tyelakh v nem.

128. **Atropin in Intestinal Obstruction.**—Stavsky concludes from the study of the literature and from the remarkable results obtained in 4 cases in his own experience, that atropin is a most valuable drug in certain cases of acute ileus. He injected subcutaneously .003 gm. atropin, followed two hours later by half the dose. The record has been favorable in 49 cases and in 9 the ileus terminated fatally. Atropin certainly deserves a trial, he states, in every case in which operation is contraindicated for any reason.

130. **Esophagotomy for Foreign Body.**—Kuzmin advises immediate recourse to external esophagotomy when a large fish bone or other foreign body with jagged edges has lodged in the esophagus. The operation is very simple and can be done by even the country practitioner without difficulty. When the wall of the esophagus is not injured by attempts at extraction, the wound heals rapidly and fluid food can be taken in two days after the operation.

New Patents.

Patents of interest to physicians, etc., October 6 and 13:

740385. Electrotherapeutic appliance. William B. Bassell, Columbus, Ohio.

740714. Apparatus for the medication of air. John Titus, Oyster Bay, and W. Titus, Old Westbury, N. Y.
741461. Pill machine. Ernest C. Clark, Detroit.
741243. Making acetate of soda. William M. Grosvenor, Edgewater Heights, N. J.
741345. Pessary. Leo Knopf, Burstadt, Germany.
741585. Producing glycerin and acidylated derivatives of aromatic bases and the product thereof. Oscar Liebreich, Berlin, Germany.
741521. Body support. William U. G. Martin, Indianapolis.
741411. Artificial leg. Ole P. R. Pold, Copenhagen, Denmark.
741371. Apparatus for the treatment of defective hearing. Guy C. Powell and A. D. Smith, Peoria, Ill.
741173. Sanitary urinal. John Seidel, Milwaukee.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

INTERNATIONAL CLINICS. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otology, Rhinology, Laryngology, Hygiene and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia, U. S. A. With the Collaboration of William Osler, M.D., Baltimore; John H. Musser, M.D., Philadelphia; James Stewart, M.D., Montreal; J. B. Murphy, M.D., Chicago; A. McPhedran, M.D., Toronto; Thomas M. Rotch, M.D., Boston; John G. Clark, M.D., Philadelphia; James J. Walsh, M.D., New York; J. W. Ballentyne, M.D., Edinburgh; John Harold, M.D., London; E. Landolt, M.D., Paris; Richard Kretz, M.D., Vienna. With Regular Correspondents in Montreal, London, Paris, Berlin, Vienna, Leipsic, Brussels and Carlsbad. Volume III. Thirteenth Series, 1903. Cloth. Pp. 305. Price, $2. Philadelphia: J. B. Lippincott Co. 1903.

GENERAL PATHOLOGY, or the Science of the Causes, Nature and Course of the Processes of Disease. By Dr. Ernest Ziegler, Professor of Pathological Anatomy and of General Pathology in the University of Freiburg, Greisgau. Translated from the Tenth Revised German Edition (Gustav Fischer, Jena, 1901) and Edited by Alfred Scott Warthin, Ph.D., M.D., Professor of Pathology and Director of the Pathological Laboratory in the University of Michigan, Ann Arbor, Mich. Profusely Illustrated. Cloth. Pp. 760. Price, $5. New York: Wm. Wood & Co. 1903.

TEXT-BOOK OF DISEASES OF THE EYE. For Students and Practitioners of Medicine. By Howard F. Hansell, A.M., M.D., Clinical Professor of Ophthalmology, Jefferson Medical College, and William M. Sweet, M.D., Demonstrator of Ophthalmology, Jefferson Medical College. With Chapters by Drs. Christian R. Holmes, Casey A. Wood and Wendell Reber. With 256 Illustrations, Including Colored Plates. Cloth. Pp. 532. Price, $4 net. Philadelphia: P. Blakiston's Son & Co. 1903.

AROMATICI E NERVINI. Nell'Alimentazione. I Condimenti, L'alcool (Vino, Birra, Liquori, Rosolli, ecc.); Il Caffè; Il Thè; Il Guarana; La Noce Di Kola, ecc. Sull'Uso Del Tabacco da Fuma e da Fiuto. By Dott. Adriano Valenti, Dell'Instituto Farmacologia Della R. Universita di Pavia. Cloth. Pp. 64. Milano: Ulrico Hoepli. 1904.

INTRODUCTION TO THE STUDY OF MALARIAL DISEASES. By Dr. Reinhold Ruge of the Imperial German Navy. Translated by P. Edgar, M.B., C. M. Edin., District Surgeon; Teluk Anson, F.M.S., and M. Eden Paul, M.D. Brux., M.R.C.S., L.R.C.P. Cloth. Pp. 137. Price, $2.75. London and New York: Rebman, Ltd. 1903.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. Designed for the Use of Students. By James Magoffin French, M.D., Lecturer on the Theory and Practice of Medicine, Medical College of Ohio. Illustrated by 10 Full-page Plates and 50 Wood Engravings. Cloth. Pp. 780. Price, $4 net. New York: Wm. Wood & Co. 1903.

THE PRACTICE OF OBSTETRICS. Designed for the Use of Students and Practitioners of Medicine. By J. Clifton Edgar, Professor of Obstetrics and Clinical Midwifery in Cornell University Medical College. With 1,221 Illustrations, Many in Colors. Cloth. Pp. 111. Price, $6. Philadelphia: P. Blakiston's Son & Co. 1903.

LA NEVRASTENIA, Con proemio del Prof. Clodomiro Bonfigli, Direttore del Manicomio di Roma. By Dott. Luigi Cappelletti, Vice-Direttore del Manicomio Provinciale di Ferrara. Milano: Ulrico Hoepli. 1904.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the two weeks ending Saturday, Oct. 24, 1903:

Brown, Orville G., first lieut. and asst.-surgeon, is relieved from duty at Fort Monroe and directed to proceed to Washington, D. C., and report at the Army General Hospital, Washington Barracks, for assignment to duty until November 3, on which date he will be relieved, to enable him to report at the Army Medical School.

Crabtree, George H., first lieut. and asst.-surgeon, now at San Francisco, is relieved from further duty in the Division of the Philippines, and will proceed to Fort Columbus for duty.

Crampton, Louis W., lieut.-colonel and D. S. G., is granted leave of absence for thirteen days from about November 1.

Ewing, Charles B., major and surgeon, will proceed to Columbus Barracks for duty, relieving Major Guy L. Edie, surgeon. Major Edie will proceed to San Francisco and report for transportation to Manila, P. I., for assignment to duty.

Edie, Guy L., major and surgeon, is granted leave of absence for three months.

Gandy, Charles M., major, is granted leave of absence for one month.

Gilchrist, Harry L., first lieut. and asst.-surgeon, now on duty with maneuver division at West Point, Ky., will proceed to Fort Riley and report to Major-General John C. Bates for duty during the maneuvers in the vicinity of that post, and, on the conclusion of the maneuvers, will return to Fort Screven.

Gaudy, Charles M., major and surgeon, now in San Francisco, is relieved from further duty in the Division of the Philippines, and will proceed to Fort Wayne for duty.

Harris, Jesse R., first lieut. and asst.-surgeon, is relieved from duty at Fort Myer, to take effect about November 20, and will report to the commanding officer of Second Cavalry for duty to accompany that regiment to Manila, P. I., for duty.

Hartsock, Frederick M., first lieut. and asst.-surgeon, will report to Lieut.-Col. Henry S. Kilbourne, D. S. G., president of the examining board at the Presidio, for examination for advancement.

Jones, John F., contract surgeon, is relieved from further duty at Fort Schuyler, and will proceed to Fort Totten for duty.

Lamson, Theodore, first lieut. and asst.-surgeon (recently appointed), will proceed from Auburndale, Mass., to Fort Myer for duty until November 3, on which date he will be relieved from duty at that station and will report at the Army Medical School for a course of instruction.

Ludington, Paul H., contract surgeon, is relieved from further duty at Omaha, and will proceed to Eagle Pass, Texas, for duty, relieving First Lieut. Park Howell.

Mansfield, Elmer E., contract surgeon, is granted an extension of leave to include November 30.

Murray, Alexander, first lieut. and asst.-surgeon, now in Washington, D. C., on leave of absence, will proceed to Fort Crook and report, not later than October 16, to the commanding officer Twenty-second Infantry for temporary duty, to accompany that regiment to Manila, P. I.

Niedman, William F. de, contract surgeon, is granted an extension of twenty days' leave.

Polhemus, Adrian S., major and surgeon, having reported his arrival at San Francisco, will proceed to Fort Crook for duty, relieving First Lieut. Charles E. Marrow, asst.-surgeon. Lieut. Marrow will proceed to Fort Sheridan for duty.

Rafferty, Ogden, major and surgeon, is relieved from duty as medical superintendent of the Army Transport Service at San Francisco and as attending surgeon in that city, and will proceed to Fort Monroe for duty, to relieve Major Richard W. Johnson, surgeon. Major Johnson will proceed to Washington, D. C., and report to the surgeon-general of the Army for instructions and assignment to duty in connection with the Medical Department exhibit at the Louisiana Purchase Exposition. The chief surgeon, Department of California, will, in addition to his present duties, perform the duty of medical superintendent of the Army Transport Service in San Francisco.

Richardson, George H., first lieut. and asst.-surgeon, is granted leave of absence for one month and ten days. The resignation of the above has been accepted, to take effect Jan. 1, 1904.

Shepherd, John M., contract surgeon, is granted an extension of leave of absence for twenty-five days.

Shaw, Henry A., major and surgeon, is relieved from duty at the U. S. General Hospital, Washington Barracks, November 1, and will proceed to Fort Adams for duty.

Truby, Willard F., first lieut. and asst.-surgeon, is relieved from duty at Fort Ethan Allen, and will proceed to Fort Preble for duty, relieving Major Charles B. Ewing.

Watkins, Victor E., contract surgeon, is relieved from duty in the Department of the Colorado and will proceed from Fort Huachuca to Eagle Pass, Texas, for duty, to relieve First Lieut. Park Howell, asst.-surgeon.

The board of officers appointed by orders of May 4 to consider certain matters pertaining to the Hospital Corps of thee Army will, as early as practicable after the termination of the maneuvers at Fort Riley, reassemble at Fort Sam Houston to complete its work, under instructions to be communicated to it by the surgeon-general of the Army. Captains Francis A. Winter and Frederick P. Reynolds, asst.-surgeons, will, on the conclusion of the maneuvers

at Fort Riley, proceed to Fort Sam Houston for this purpose, and, on the completion of the work of the board, will return to their respective stations.

The following named assistant surgeons are relieved from duty at the posts designated, and will repair to Washington, D. C., and report, November 3, at the Army Medical Museum Building, to Col. Charles L. Heizman, A. S. G., president of the faculty of the Army Medical School, for a course of instruction at that school: First Lieuts. Henry S. Klersted, Fort Miley; Jay R. Shook, Fort Myer; Henry E. Noble, Fort Sheridan; James W. Van Dusen, Columbus Barracks; Park Howell, Eagle Pass; Reuben B. Miller, San Francisco; James I. Mabee, Presidio; Percy L. Jones, Fort Rodman; Fred W. Palmer, Jefferson Barracks; Edward B. Vedder, Fort Columbus; Henry F. Pipes, Fort Totten; Charles L. Foster, Fort Myer; John R. Besley, Fort McPherson; Robert C. Loving, Fort Leavenworth; Chester J. Stedman, Fort Adams; Orville G. Brown, Fort Monroe; George F. Jueneneano, Fort Columbus; Joseph F. Siler, Fort McPherson; Arthur M. Whaley, Fort Sheridan.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Oct. 24, 1903:

P. A. Surgeon B. L. Wright, commissioned a passed assistant surgeon from March 3, 1903.

Asst.-Surgeons F. M. Bogan, J. H. Payne, Jr., and J. J. Snyder, commissioned passed assistant surgeons from June 7, 1903.

Drs. J. Miller, Jr., E. C. Taylor, F. E. Campbell, J. E. Gill and I. S. K. Reeves, appointed assistant surgeons from Oct. 12, 1903.

Asst.-Surgeon W. S. Pugh, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Pharmacist J. Cowan, retired from active service, Oct. 19, 1903, under the provision of Section 1453, R. S.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the twenty-one days ended Oct. 22, 1903:

Surgeon Preston H. Bailhache, detailed to represent the service at the meeting of the American Public Health Association at Washington, D. C., October 26.

Surgeon D. A. Carmichael, granted leave of absence for thirty days from October 16.

Surgeon F. C. Kalloch, granted leave of absence for three days.

Surgeon J. H. White, to proceed to Gulf Quarantine Station and assume temporary charge.

Surgeon P. M. Carrington, granted two days' leave of absence from October 15, under paragraph 189 of the Regulations.

Surgeon G. M. Magruder, granted extension of leave of absence, on account of sickness, for two weeks from October 7.

P. A. Surgeon C. P. Wertenbaker, to proceed to Beaumont and Houston, Texas, for special temporary duty, October 2. To proceed to El Paso, Texas, for special temporary duty.

P. A. Surgeon J. C. Perry, to proceed to Charlestown, W. Va., for special temporary duty.

P. A. Surgeon B. C. Brown, granted leave of absence for one day, October 18.

P. A. Surgeon J. A. Nydegger, Bureau letter of September 4, granting him leave of absence for one month from September 13, amended so that said leave shall be for one month from September 23. Granted leave of absence for ten days, on account of sickness, from September 13.

P. A. Surgeon H. S. Mathewson, department letter of September 23, granting him leave of absence for forty-five days from September 22, amended so that said leave shall be for forty-five days from October 3.

P. A. Surgeon S. B. Grubbs, granted leave of absence for five days.

P. A. Surgeon L. L. Lumsden, to proceed to Beaumont, Texas, for special temporary duty, October 2. To proceed to Eagle Pass, Texas, for special temporary duty, October 5. To proceed to El Paso, Texas, and assume temporary charge of the station, October 13.

P. A. Surgeon J. F. Anderson, to proceed to Baltimore for special temporary duty, October 1.

P. A. Surgeon L. D. Fricks, granted leave of absence for one month from November 1.

Asst.-Surgeon T. F. Richardson, to proceed to San Antonio, Texas, for special temporary duty, October 21.

Asst.-Surgeon F. W. King, detailed as inspector of unserviceable property at Ponce, P. R.

Asst.-Surgeon Edward Francis, to proceed to the City of Mexico, Mexico, for special temporary duty, October 6.

Asst.-Surgeon L. P. H. Bahrenburg, granted leave of absence for seven days from October 14 under paragraph 191 of the Regulations. Granted extension of leave of absence for seven days from October 22.

A. A. Surgeon C. B. Ford, granted leave of absence for three days from October 24.

A. A. Surgeon B. W. Goldsborough, Department letter of September 10 granting him leave of absence for three weeks from September 10, amended so that said leave shall be for three weeks from September 22.

A. A. Surgeon J. M. Jackson, granted leave of absence for thirty days from October 5.

A. A. Surgeon H. C. Sibree, granted leave of absence for six days from October 6.

A. A. Surgeon J. G. Stanton, granted leave of absence for thirty days from October 10.

Pharmacist F. L. Brown, to proceed to St. Louis and report to medical officer in command for temporary duty, October 10.

Pharmacist F. S. Goodman, to proceed to Laredo, Texas, and report to Surgeon G. M. Guiteras for special temporary duty as special disbursing agent, October 2.

Pharmacist S. W. Richardson, Department letter of September 15, granting him leave of absence for ten days, revoked. To proceed to New York City and Providence, R. I., for special temporary duty, October 14.

Pharmacist C. H. Woods, to rejoin station at Chicago, October 10.

Pharmacist M. R. Mason, relieved from duty at Nome, Alaska, and directed to proceed to San Francisco and report to medical officer in command for duty, October 8.

PROMOTION.

G. A. Morris, pharmacist of the third class, promoted to be pharmacist of the second class, effective September 3.

Charles Maples Steger, recommissioned as assistant surgeon in the Public Health and Marine-Hospital Service to correct original commission, effective September 16.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Oct. 23, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, Oct. 4-10, 1 case.
Colorado: Denver, Aug. 29-Sept. 26, 4 cases.
Florida: Jacksonville, Oct. 11-17, 1 case.
Illinois: Chicago, Oct. 11-17, 3 cases; Danville, Oct. 11-17, 1 case.
Louisiana: New Orleans, Oct. 11-17, 2 cases, imported.
Maryland: Baltimore, Oct. 11-17, 1 case.
Mississippi: Natchez, Oct. 12-19, 1 case.
Missouri: St. Louis, Oct. 3-10, 2 cases.
New Hampshire: Manchester, Oct. 11-17, 3 cases.
New Jersey: Camden, Oct. 11-17, 1 case.
Ohio: Cincinnati, Oct. 9-16, 2 cases; Cleveland, Oct. 11-17, 1 case.
Pennsylvania: Altoona, Oct. 11-17, 1 case; Johnstown, Oct. 11-17, 14 cases; Philadelphia, Oct. 11-17, 54 cases, 4 deaths; Pittsburg, Sept. 12-Oct. 17, 279 cases, 60 deaths, 7 cases imported.
South Carolina: Charleston, Oct. 11-17, 1 case, 1 death.
West Virginia: Jefferson County, Oct. 1-15, 14 cases; Wheeling, July 1-Sept. 30, 4 cases, 2 deaths.
Wisconsin: Milwaukee, Oct. 11-17, 9 cases.

SMALLPOX—INSULAR.

Philippine Islands: Cebu, Aug. 1-31, 8 cases, 4 deaths; Manila, Aug. 30-Sept. 12, 3 deaths.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Aug. 16-Sept. 15, 23 deaths; Rio de Janeiro, Sept. 14-27, 109 cases, 40 deaths.
Chile: Antofogasta, Aug. 25-31, 9 deaths.
Colombia: Barranquilla, Sept. 28-Oct. 4, 2 deaths.
Formosa: Aug. 1-31, 1 case.
Great Britain: Birmingham, Sept. 27-Oct. 3, 9 cases; Bristol, Sept. 27-Oct. 3, 1 case; Glasgow, Oct. 2-9, 1 case; Leeds, Oct. 4-10, 4 cases; Liverpool, Sept. 27-Oct. 3, 8 cases; London, Sept. 27-Oct. 3, 1 case; Manchester, Sept. 27-Oct. 3, 2 cases; Newcastle-on-Tyne, Sept. 27-Oct. 3, 5 cases, 1 death.
Malta: Sept. 20-26, 6 cases.
Mexico: City of Mexico, Sept. 28-Oct. 11, 5 cases, 4 deaths; Merida, Oct. 11, 1 case.
Russia: Odessa, Sept. 27-Oct. 3, 1 death; St. Petersburg, Sept. 20-26, 19 cases, 2 deaths; Warsaw, Aug. 28-Sept. 12, 7 deaths.
Spain: Barcelona, Sept. 27-Oct. 3, 4 deaths.
Turkey: Constantinople, Sept. 28-Oct. 4, 3 deaths; Smyrna, Sept. 28-Oct. 4, 77 deaths.
Venezuela: Yaritagua, Sept. 23, prevalent.

YELLOW FEVER—UNITED STATES.

Texas: Connell, Oct. 20, 1 case; Castroville, Oct. 21, 1 case; Hondo, Oct. 19, 1 case; Laredo, Oct. 14-21, 98 cases, 7 deaths; San Antonio, to Oct. 21, 13 cases, 3 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Sept. 14-27, 5 cases, 3 deaths.
Mexico: City of Mexico, Sept. 28-Oct. 4, 1 case, 1 death; Merida, Oct. 4, 14 cases; Nuevo Laredo, Oct. 13-21, 14 cases, 2 deaths; Progreso, Oct. 4-11, 2 cases; Tampico, Sept. 30-Oct. 10, 6 deaths; Vera Cruz, Oct. 3-10, 38 cases, 11 deaths.
Venezuela: Puerto Cabello, Sept. 20-26, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Aug. 30-Sept. 12, 94 cases, 76 deaths; provinces, Aug. 30-Sept. 12, 1,614 cases, 1,394 deaths.

CHOLERA—FOREIGN.

China: Hankow, Sept. 12-19, 1 case, 1 death; Hongkong, Sept. 5, 1 death; Shanghai, Oct. 12-19, 21 deaths; Tientsin, Sept. 12-19, 3 cases, 1 death.
India: Calcutta, Sept. 6-12, 4 deaths; Madras, Sept. 6-12, 3 deaths.
Straits Settlements: Singapore, Aug. 29-Sept. 5, 11 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Oct. 7, 1 case, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Cebu, Aug. 19-Sept. 12, 6 cases, 3 deaths; Manila, Aug. 30-Sept. 12, 3 cases, 3 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Sept. 14-27, 62 cases, 24 deaths.
Chile: Iquique, Aug. 28-Sept. 11, 9 cases, 5 deaths.
China: Newchwang, Sept. 12-19, 73 cases, 62 deaths.
Egypt: Alexandria, Sept. 12-18, 8 cases, 4 deaths; Damiette, Sept. 12-19, 1 case, 1 death.
Formosa: June 1-Aug. 31, 164 cases, 142 deaths.
India: Calcutta, Sept. 6-12, 13 deaths.
Italy: Licata, Sept. 13-20, 1 case, 1 death.

In the report to the journals for September 19, 11 cases of smallpox were accredited to Ogden, Utah, when there should have been only 1.

RELATION OF THE PUBLIC SCHOOL TO THE SEMINARY AND COLLEGE AS TO PSYCHOSES.*

F. SAVARY PEARCE, M.D.

Professor of Nervous and Mental Diseases in the Medico-Chirurgical College.

PHILADELPHIA.

This topic is an important one to the educator and to the parent or guardian of the growing youth of our fair land, America, which claims so justly to be a leader in earthly pursuits. That we are going a little too rapidly toward progression of the mind in these almost too strenuous days of advancement is pretty clear to the thinker or man of larger experience. The result of "wear and tear" on the nervous system must be remembered to be much greater in youths from 14 to 18 years, i. e., during the development of adolescence with its wonderful attendant physiologic, physical and psychic readjustment of the organization. The paper written on this subject must not include as a fundamental basis for study the hardy westerners' children of the plains, nor the country school boy who is forced to healthy physical exercise in his trudging along the country roads, perhaps knee deep in mud or snow; but the overwrought child of the cities. These latter are the object of our attack in the endeavor to retain for them a full component of nervous health—"For with health departing all else flows." The vast majority of youths are educated in the cities where the comforts of home become almost too seductive in many instances, and the precocious boy may entirely eschew physical exertion in his early endeavor toward mental culture. We shall try to speak, therefore, for this vast majority, purposely leaving out of the consideration study of the extremes, i. e., the robust individual under more normal mental and physical surroundings and the extremely delicate child, on the other hand; also the more distinctly neurotic type. It would not be fair in such a discussion to-day to include any of these classes. It is after all a most difficult subject you have selected for discussion.

It has been my experience in observing the average American boy or girl who passes from the city grammar school to high school and finally to the academy or college that there is a wide variance in the methods of instruction, brought about largely in many instances by the idiosyncrasy, say, of a school board or board of trustees, no doubt due to their peculiar ideas of and efforts to teach the student by some special method which seems to the said bodies recited to be the most productive of best results in educatory lines. Of course, this *modus operandi* is carried out in detail by the many teachers who are instructed in the same methods. Thus the widespread good or ill that may result! In these days of rapid advance, we repeat, there is apt to be too much stress laid on particular methods of instruction, which is the old story of specialism becoming lopsided and too pedantic. Of course, the greatest trouble lies in the fact that growing youths are often put to tasks which their brains can never compass; and a great many times psychoses in children and early adult life can be laid at the feet of the general practitioner who did not prove the wise guard he should be through advisory measures to parents, where a child is becoming nervous from misdirected instruction and overwork of the nervous system. The medical profession must, therefore, be awakened more keenly to its ultimate duties to the civic throng if highest common-sense methods of instruction are ever to prevail toward training the individual to be the most useful member of society.

The average child, I am sure, is forced too much at his work even in grammar schools among public institutions; and, from the neurologist's standpoint, I am convinced that such children in the cities would do better to have one session in school than be compelled to rush to a midday meal often of indifferent quality, then to go back again within an hour to recitation, which necessarily requires the freest circulation in that important organ, the brain, to the great detriment of digestion which is, of course, ill carried on under such abnormal circumstances. One-half of the general aches and pains, including headaches, are due to disturbance of metabolism from these various causes in which correction of the eyes by refraction can only in part relieve. Better be that the child have superabundance of fresh air and physical exercise than a doubtful mental advancement, as it is when associated with a nervous, disabled constitution. As remedial measures, I could especially hope that in the high schools of the country at least this régime might be carried out; or a second session, if held, be devoted to classes in natural history, or probably to modified physical gymnastics. As to this latter, I wish to sound a word of caution, since the zealous physical instructors in all educational institutions have, in my experience, been led through too narrow specialism into the error again of overwork of muscles, which the physiologist knows will weaken or finally exhaust the central nervous system; if it does not, indeed, as in some instances I know very well of, produce physical disability such as a dilated or irritable heart that is much worse than asthenia, the result of primary mental exhaustion, and more difficult to rightly interpret or cure.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

We believe that there is less of overwork (and, therefore, less hysteria, neurasthenia, accompanying melancholias, delusional insanities, particularly in the class of which we speak) in academies and preparatory schools than there is in the high schools, or even in the college, the place of advanced training, to which we have referred above; although the danger is patent enough in all educational institutions. This disproportion of wear and tear is due to the fact that the academy and preparatory school are ministered over by those who have not so much at heart competition in class work for their institutions; and that many of them are in suburban districts, where the youth from the cities are inspired by the open air and pastoral surroundings, as well as invigorated by the same natural exercises thus invitingly placed before them. It is much more difficult, as I can cite cases to support, for the average student to pass from the high school to college than for the academically trained boy or girl to take up lines of instruction in the college. And this is the result of overwrought nervous systems by the greater urging to work with too little play, which will frequently "make Jack a dull boy" indeed; and sometimes a neuropathic product, a hysteric, or a case of hebephrenia, or some other form of mental alienation.

The object of writing this paper has been not to give you intricate details of what subjects are pushed too rapidly on the growing youth, who has so many demands on his time, but the endeavor has been made to enforce what I feel to be a certain truth from observation through practicing neurology; i. e., that students of the United States generally (particularly those who are slightly below par physically and, in consequence, of lower nerve tone) are much overwrought. The essential point of this contribution, therefore, that I wish to impress is that we, as practitioners of medicine, desiring to keep the community well of all ailments, must assume greater responsibility in civic affairs if for no other reason than to conserve the public health—the excuse and reason for our existence. If the physician will (knowing as he does well enough these facts of overwork of children, the cause of hysteria, melancholia and the more frank insanities at times) deign to become a missionary to the good cause, in the only way that can be of avail for right methods, he will join with the intelligent educators and interested people in the community in which he resides, volunteering his opinion through public lectures before civic clubs and the like, which are doing so much universal good and for which credit must be given to intelligent womanhood. As long as the physician withholds his active influence in these matters, believing he has no legitimate place outside of prescribing, so long will a large burden of the blame for existing conditions be laid at his feet.

I will not detain you with more than these remarks, feeling that in them, from my standpoint at least, the germ of the matter has been recognized. We shall hope that in the discussion ways and means will be suggested by those more competent; and that the result of the symposium will make for proper correction of present-day methods of education of youth.

Habitual Epistaxis.—In habitual epistaxis, without regard to the cause, the frequency of the attacks, or their severity, Woodward says ammonium carbonate is an absolute specific. Two grains every ten minutes will stop the flow quickly during the attack. To correct the tendency and overcome the habit, 2 grains should be given from three to six times each day.—*Medical Summary.*

BEST METHODS OF COUNTERACTING PSYCHOSES DUE TO THE STRAIN AND STRESS INCIDENT TO OUR PUBLIC SCHOOL METHODS.*

WILLIAM JAMES HERDMAN, M.D., LL.D.
ANN ARBOR, MICH.

A matter so important as the education and development of children calls for the highest intelligence and wisdom of mankind. It is so vital to the welfare of the race that no one profession can arrogate to itself the right of exclusive control or dictation as to the methods to be employed. The object sought should have the benefit of the combined wisdom and experience of all professions which have anything of value to contribute from their discoveries that has a bearing on the subject.

The members of the medical profession justly and rightly consider that on them rests the responsibility of searching out the causes of diseases of whatever sort, mental as well as physical, and of directing the attention of the public to the appropriate means for their prevention, and it is a healthful sign of vigorous activity and normal advancement of the work of that profession when its members are found interesting themselves in tracing causes to their fountain head, where effective healing or preventive measures are alone possible, and not waiting until such time as the damage is done and curative means are unavailing, and energy and enthusiasm are expended hopelessly. This is commendable zeal on the part of the members of the medical profession and unselfish devotion to duty, and the thoughtful person can not fail to recognize in it the exercise of the highest function of the healing art—the prevention of all abnormality.

But in bringing our medical experience and methods of observation to bear on questions which do not lie directly or wholly within their sphere, but rightly belong to a profession whose members must be credited with equal intelligence and quite as earnest devotion to their peculiar work, we must guard against overstepping the bounds of legitimate criticism and keep strictly within the limits where our training and experience justify us in speaking with authority. The very importance of the subject of education and its methods demands that we apply to it our most exact methods of research and see to it that our conclusions are drawn from unassailable premises. In considering, therefore, the special subject at present under discussion it is for us to determine first what, if any, are "the psychoses which result from the strain and stress of public school methods."

As far as I have been able to discover from the sources of information accessible by me, and in the time at my disposal since this topic was assigned to me, no reliable data are extant bearing directly on the subject. Eight years ago Dr. Alfred Spitzner of Leipsic declared in a carefully prepared and learned article: "As far as I know, there is no such thing as a comprehensive, officially organized investigation and compilation of facts referring to the existence and cause of nervousness among school children." And still more recently (Dec. 16, 1901) Dr. Edward M. Hartwell, secretary of the Boston Statistics Department, said in a paper read before the Boston Society for Medical Improvement: "So far as I can learn, the only states in which thorough-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

going, scientific investigations of the effects of school life on the school population have been made are Sweden and Denmark." In these countries commissioners were appointed ten or twelve years ago who made investigations and reports abounding in most instructive statistical tables and valuable information as to the results of certain educational methods, but these reports contained little that had any bearing on the subject of this discussion.

Within the past year a special committee has been appointed by the British Association for the Advancement of Science "to consider the condition of health essential to carry on the work of instruction in schools," and this committee has undertaken to collect information as follows:

1. Records of original observations on the periods of day appropriate for different studies, the length of lessons, and the period of study suitable for children of different ages.

2. On anthropometric forms in use in various schools with a view to preparing a typical form for general use.

3. On anthropometric and physiologic observations recorded in different schools for a series of years on the same children.

4. Recorded investigations into the causes of defective eyesight in school children, and a definition of the conditions necessary for preserving the sight.

5. An inquiry into the practical knowledge of hygiene possessed by school teachers.

It would seem from the statements of these persons who are in a position to know what has been done in this line of investigation, and from what is being attempted, but not yet accomplished, in the way of gathering facts by one of the ablest bodies of scientific men in existence, that while the need of exact information on this subject is beginning to be very generally felt, yet it is an acknowledgment that, so far, no exact information is at hand such as is necessary to locate causes and serve as a basis to institute reforms, if any are needed.

Public school methods can not be justly charged with either the development or aggravation of psychoses in the children subjected to them until we can eliminate as causative factors: 1, Conditions that antedated the school period and its influences on the child, and, 2, such causes as may be operating on the child outside of school hours and school environment.

Assuming that psychoses can be demonstrated to exist among school children and that nervous affections increase in proportion to the time spent under school conditions, as is claimed by many, obviously the school methods can not justly be held responsible for the entire result when the causative factors entering into the problem are so many and so various. We must here, as in all attempts at exact analysis, devise some method by which each causative factor can be discovered and its relative value in effecting the result be properly estimated.

As to the fact of the existence of psychoses among school children sufficient reliable testimony is furnished us. While no systematic and authoritatively organized effort has been made to determine this in any quarter, sporadic attempts by medical men of unquestioned integrity and ability have been made in many places in recent years which have furnished evidence sufficient to show beyond all question that both physical and mental abnormalities exist among school children.

Among the physical defects to which attention has been more especially directed and careful investigations made by physicians are the abnormalities of the special senses, chiefly those of sight and hearing, since these are the main avenues by which the world of sense finds entrance to the world of mind. "All the raw material of thought comes through the senses. All the raw material acted on by memory, imagination, judgment, comparison and reasoning is gained through sense experiences." It is of primary importance, therefore, to a correct and symmetrical development of all the mental faculties that the sense mechanism furnished for the transmission of this raw material be in perfect working order, so that it may honestly deliver to the mind for its use every attribute which the world of things possesses which can through sense perception be apprehended.

Tests for the detection of defects in vision have reached such a degree of accuracy and are so convenient in application that they have afforded the most ready means of examining school children as to the integrity of sense perception. The relatively greater importance of this special sense as compared with others in the acquirement of accurate knowledge of external things likewise renders it well fitted to demonstrate the need of attention to these physical channels which furnish the pabulum for educational development. For while to none of the other senses has the same amount of attention been directed in these investigations, it is safe to assume that when the searchlight of scientific observation is brought to bear on them their integrity will be of no higher order than that which has been shown for the sense of sight. Dr. Wright,[1] health officer of New Haven, Conn., makes the statement that "it has been found by the examination of the eyes of many thousand children in the high schools of Europe that over 40 per cent. were nearsighted to a greater or less extent. It was also found that the defect increased from the primary to the higher grades not only in frequency but in degree."

Dr. Jane Kelly Sabine[2] of Boston gives as a result of observations made on 2,000 girls in schools and colleges of New England, among whom 30 per cent. were either wearing glasses or were ordered to have their eyes examined by a specialist, that there were 6 per cent. with defective hearing, 5 per cent. with weak lungs, 4 per cent. with heart trouble, 75 per cent. with menstrual troubles and 90 per cent. with leucorrhea.

Dr. G. B. Saunders of New Zealand,[3] in an elaborate report of investigations made by him and others on the vision of school children, concludes: "It has been clearly established by the evidence set forth from these statistics that defective vision is induced during the whole period of school life and that children entering school with healthy eyes have developed faulty vision, and that the proportionate number of the scholars affected increases as we ascend in the classes and also in the grade of the school."

While I am disposed to question the assertion of Dr. Saunders that these children, or any number of them, had "healthy" eyes at the time they entered school, since no evidence was given that examination of these children on beginning school was made, yet the fact remains—and abundant testimony other than this I have

1. Boston Med. and Surg. Jour., March 27, 1902.
2. Paper before the Society for Medical Improvement, Dec. 16, 1901.
3. London Lancet, Jan. 11, 1902.

offered can be furnished in support of it—that the eyesight of from one-fourth to one-third of all school children is defective, and, moreover, such defect has in many instances been brought to the knowledge of both teacher and parent for the first time by these inspections instituted by physicians.

Whether or not the production of this large percentage of cases of impaired vision can in any measure be charged to school methods or defective school hygiene must, I think, for the present, be left an open question. It is for the present sufficient, perhaps, for us to know that such a large share of school children at an early age are handicapped by serious deficiencies in the mechanism of one of the most important senses through which knowledge is acquired, and that often such deficiencies remain unrecognized and uncorrected, as far as such correction is possible, by both parent and teacher.

Now, it is needless for me to recall the fact that eyestrain is one of the quickest and surest means for bringing about brain exhaustion and mental fatigue and that out of the fruitful soil of mental fatigue all manner of psychoneuroses spring up. What would appear, and in reality be, a very simple task to a child healthy in every organ, might in one with defective vision produce a strain and stress that would cause an unhealthful drain on the entire store of nerve energy and so result in disorder of normal function in certain of the more susceptible parts. It is not surprising, therefore, to find many children who are victims of visual defects unable to bear the strain of ordinary school requirements, without manifesting signs of neurasthenia, hysteria, or some form of mental or motor instability, or both, the fault lying in the vulnerability of the child and not in the school method. But investigation seems to show also that the constant demand made on the sense of sight by the confinement of school methods of instruction to the printed page as a source of information has resulted in a still further deterioration of this sense organ, as is seen from the greater degree of myopia, as well as the increase in relative frequency of this as of other visual defects, among pupils in the higher grades. If it can be shown that the healthy and normal eye is caused to deteriorate by excessive use or strain due to school requirements, and, further, that the same educational results could be attained by informing the mind through some other avenue of approach, as the ear, the touch or the muscular sense, we would then be justified in finding fault with the method which throws undue labor on an important organ, not only to its injury but to the injury of the organism as a whole. Therefore, no matter what the outcome is in the way of nervous or mental manifestations of an abnormal kind in school children with demonstrable physical defects, unless it can be shown that such physical defects and their consequent nervous disorders are either caused, or are unnecessarily aggravated, by the school methods employed, it must be assumed that the neuroses and psychoses accompanying them would have developed in spite of school methods or under any circumstance where the same demands would have been made on the organism with a view of securing the educational result desired.

There are conditions existing in many school rooms which are injurious to the eyesight aside from the prolonged and, perhaps, unnecessary confinement to the printed page. Dim or misdirected light, the distance of the pupil from the visual demonstration on the blackboard, defective ventilation and temperature of the room are causes which may contribute very considerably to the strain produced not only on this sense alone but on the nervous system as a whole. But these are matters of school hygiene which, although they have an important bearing in causing the effects we are considering, do not properly enter into the plan of this discussion. It has been seen that the special sense strain is very generally recognized as a fruitful source of mental fatigue and consequently of the various pyschoneuroses that accompany this state or stand as the evidences of it.

Next to this as a causative physical factor in bringing about a reduction of nerve energy in girls must be placed the disorders of menstruation and an unhealthful state of the generative organs. The very large percentage of menstrual troubles and of leucorrhea reported by Dr. Sabine as present in the 2,000 girls from whom her statistics were gathered, directs attention to a most significant fact. My experience for more than a quarter of a century in caring for and observing the health of a large number of college girls gives emphasis to this as a causative factor in the development of psychoneuroses among school girls. While the inflexibility of school requirements must act as one of the factors in maintaining and, perhaps, in creating this unhealthful physical state among our girls in some instances, yet we are well aware that there are many more potent causes such as unsuitable dress, social excesses, indiscretions in diet, neglect of sleep and of the bodily needs, contributing to the result to a much greater degree.

Could the teacher understand the nature and signs of the extra physical strain to which so large a per cent. of the female pupils are periodically subjected, and was she free to temper the demands of the curriculum to meet the condition, much injury would be avoided. But here again, as in the case of defective eyesight, the responsibility for the result produced on the nervous system must be shared by the parents, the guardians and the pupils themselves, and not charged wholly to the teacher's account or assumed to be due to a faulty school method.

There is another phase of this problem which is deserving of much more serious and systematic attention, both from the teacher and the physician, than it has hitherto received, and that is the natural evolution of the child mind and the stages at which certain capacities are most active and vigorous and capable of performing their function with the least friction and expenditure of nerve force.

It is here, in my opinion, that our pedagogic methods in this country are most open to just criticism, since the proper adjustment of studies, the proper period of the day for each and the length of time they should occupy, are questions which a scientific pedagogy should have long since settled beyond all controversy.

It ought not to require the physician to call the attention of the teacher to the fact that nature study, which engages sense perception, creates interest, attention and enthusiasm, naturally precedes, in a well-arranged curriculum, the relation of numbers and comparison of abstract attributes. In other words, that the acquisitions by the senses must lay a broad and deep foundation before the moral and reasoning faculties can properly evolve, and, moreover, that a child possesses avenues for sense perception other than those of sight and hearing, mainly those of touch and muscle sense, which have a value quite equal to either of the former in creating mental stability, though that value is supplementary, and not substitutive.

It should long since have been established beyond all question by teachers that the acquisition of language is an early capacity of the child mind, the naming of things being only secondary to their apprehension by the senses, and that thoughts concerning things must have the language symbols as a necessary foundation for the expression of those thoughts or even of clear conceptions concerning them. When we look abroad from this point of view—of the natural evolution of the child mind—over the school methods that are in operation we find them still in a chaotic state, "without form and void." No settled principles appear to have been evolved as to the natural order of studies after centuries of our best thought have been devoted to the solution of the problems of education.

And yet every observing teacher has had the evidence daily before her that a course of study must be in harmony with these processes of development in order to be successful.

More depends on the order of studies assigned than on the contents of the studies themselves. You have heard of the experiment made some years ago by four teachers in the city of Paris, in a school for boys (the Lycée). They asked permission of the Minister of Education that each of them might give to his 25 pupils the same studies prescribed in the required course, but in a different order, an order believed by them to accord with the natural development of a boy's mind rather than in the arbitrary order hitherto demanded. "These boys completed all the required studies in this natural order in three and a half years, instead of seven years, the time assigned for the completion of the course as regularly given. On examination, they were found to be equally proficient mentally, and above the average in physical development, as compared with those who had spent seven years in going over the same ground."

This one striking illustration furnishes convincing proof that the study of the natural history of the child, the manner and order of its physical and mental unfolding, is an indispensable prerequisite to the right exercise of a teacher's functions.

Periods of study too prolonged and a disregard of the vital waves of alertness and acquisitive capacity, which are likewise faults that can now be justly charged to the account of the school methods in many places, and which operate in no small degree as mental irritants and mental worries would, by a better understanding of the immature stages of childhood, be corrected.

I can but sum up the thought I have attempted to present to you on this phase of my subject by quoting the words of Herbert Spencer: "What with perceptions unnaturally dulled by early thwartings and a coerced attention to books; what with the mental confusion produced by teaching subjects before they can be understood, and in each of them giving generalizations before the facts of which these are the generalizations; what with making the pupil a mere passive recipient of other's ideas and not leading him to be an active inquirer; and what with taxing the mind to excess, there are few minds so efficient as they might be."

In the light of these considerations, it is evident that the end, which we, as physicians, seek—the arrest of such causes as lead to the mental and nerve irritability and physical weakness which we observe in school children—must have a plan of correction sufficiently comprehensive.

We need to know more of the child before it is subjected to public school conditions and more of the influences that attend it outside of school hours. Only by having such knowledge can we properly estimate the effects of school conditions for good or evil.

In attempting to formulate a plan for the removal of the physical and mental defects we have observed, I would suggest:

1. A careful medical inspection of school children at the beginning of their school life and at stated intervals thereafter, covering both their physical and mental capacities.

2. All teachers should be well instructed in the physiology and psychology of the child and in the principles of school hygiene..

3. School buildings and their environments should be made to comply with all the requirements of modern school hygiene, as to light, pure air, temperature, seating, decorations, play ground facilities, etc.

4. The curriculum should be so flexible as to allow more opportunity for the exercise of the individual judgment of the teacher, as to the best method to adopt for each child in order to secure for it the greatest educational value, and the curriculum should include facilities for appealing to the mental faculties along every sensory pathway, among which facilities I would mention nature study, rational kindergarten, manual training and physical exercise.

5. The number of pupils assigned to any one teacher should be only such as she can care for to the best advantage. Time should be allowed the teacher for a careful study of the physical and mental needs of each pupil.

6. A closer relationship between the parent and teacher, with a view of securing the end sought—the highest and most useful development of the child.

7. The removal, as far as possible, of all conditions within or without the school room that interfere with the accomplishment of this purpose.

DISCUSSION

ON THE PAPERS OF DRS. PEARCE AND HERDMAN.

Dr. Harold N. Moyer, Chicago—Before this Section, three years ago, I presented a paper on the psychoses of chorea. In 8 out of 10 cases there was a psychosis—not that the children were demented or incoherent, but there was a distinct alteration in the mental condition of the child during the continuance of the chorea. What is true of chorea is true of many children's diseases, both of the nervous system and of the nutritional disorders which are so common in infancy. The psychoses of children is a much-neglected subject, meaning by this the minor, less accentuated deviations from the normal, and not what is commonly termed insanity. The psychoses of childhood are not incidental to any great extent to school strain or to any strain, but they are due to the developmental period, *per se*, primary defects in the nutritional processes in early life and a bad heredity.

Is strain a bad thing? Is the use of an organ, whether it be the brain, or the heart, or the lungs, or the stomach, a bad thing for that organ? I am distinctly of the opinion that it is not. I believe that the use of organs strengthens them, and that the only way organs are strengthened is by use; but we must stop short of strain. Is the early breakdown of the athlete due to strain? Is it not due to the fact that there is a maladjustment of certain organs? He has developed organs which are no longer needed, and when he passes the age of youth, those organs tend to atrophy and decay when the strain is no longer put on them. After all, we get down to the nutritional factor, which teaches that we should put such an amount of work on an organ as it will stand, and lead to its development, and that will not carry it beyond a point that will be needed afterward. That is an underlying

principle of pedagogy. The supplemental factors—the defects in the nose, throat, eyes, etc, with which the child may be handicapped—are the individual peculiarities of cases and must be eliminated. The common factor is nutrition, the strengthening of the organs by proper use, to secure a symmetrical development. The development of the nervous system at the expense of the muscular and vegetative systems is a fault of modern methods of education, but it is being rapidly corrected. We must not fall into the opposite extreme and neglect the nervous system, remembering that the use of an organ strengthens and develops it.

DR. JOHN PUNTON, Kansas City—The medical profession should take a more active part in the regulation of the methods of public school education. There is great need of a consensus of medical opinion, but nothing of a tangible character has been done. About ten years ago I suggested that every large city should maintain a board of medical inspectors. A year or two later the first board of this kind was appointed in Boston, and later other cities followed suit. In spite of that there are many cities that have failed to give even so much recognition to the subject. Three or four years ago I read a paper before the American Neurological Association, desiring to get them interested, but unfortunately nothing was done. It has been proved by the medical school inspectors that anthropometric measurements show a physical basis for precocity on one hand and for mental dulness on the other. If we could introduce this system in all schools it seems to me that hysteria and other neuroses could, in many cases, be prevented. Along those lines the present system of medical inspection is lame. Certain definite standards of weights and measures would be of vast importance. It is now usually taken for granted that like age implies like mental capacity, which is a wrong criterion, because mental development occurs in different degrees at different ages in different individuals, and as the public schools deal with all classes of children this standard is very misleading. I do not think, however, that the public school methods are altogether to blame for the nervous diseases. The child's home life has much to do with it, and very often the parents are more to blame than the teachers. Very often the teachers are to blame independent of the methods which are enforced by the educational system of the city; for instance, when children have fallen behind in their studies the teacher will sometimes give private instruction, and parents are often very anxious to have her do so, because they do not wish their children to be put back or to fail of promotion. I think such a teacher deserves severe criticism. I also find that some teachers, to stimulate the best efforts, will offer prizes for those who stand highest in examinations. That is a wrong method; it puts a severe mental strain on all the children, whether they win the coveted prize or not. The defects among public school children can be classified into physical and mental. The former may give rise to very serious misunderstanding. Some physical defects pertain to the bony structure and sometimes militate against nutritional growth. We must set a definite standard by which we can separate the normal child from the abnormal. There are differences of degree and kind from the normal child up to the precocious and down to the worst dullard, and physically we also have all types. All such defects have some influence on the development of the child, and it seems to me that the medical aspect of school education must be worked out along this line by the medical profession. Now that this Section has taken up the subject, I hope that something will be done in a tangible way, so that the public can get a consensus of medical opinion.

DR. J. H. MCBRIDE, Pasadena, Cal.—Some years ago Dr. Porter, now professor of physiology in Harvard, made some very interesting investigations into the health of 35,000, I think, school children of St. Louis. He discussed one element of the problem under "The Physical Basis of Precocity and Dulness in Relation to Sex and Age." He found that the children who were taller and heavier were the brighter children; that the dull children were shorter and weighed less. Dr. Byers, a surgeon in the Navy and formerly at the Annapolis Academy, found that by special training he could make students grow taller than the average. He claimed to be able to add an inch to the height of a person between the years of 16 and 20. It is an important fact in the economy of child life that the physical development is directly related to the mental development. Other things being equal, the man who has well-drilled muscles and a thoroughly developed body will be a smarter man because of it. Much of the so-called overstudy of school children and the overwork of men is not properly overwork or overstudy. It is due to unhygienic living. If people would live as they ought, eat, sleep and exercise wisely, there is little danger of harm from any amount of work they can do. The worst fault of our public schools is the lack of gymnasiums and manual training. We need both badly. We have forgotten the body in our fussy anxiety about the mind. President Jordan of Stanford University has informed me that the students there improve in health during their stay in college. The physical life of the students is carefully attended to.

DR. R. C. MOORE, Omaha—Little children of 5 years and even younger are sent to the kindergarten, where for hours they are confined to the house, placed under restraint and curbed in their childish plays. This is all wrong. We can go to the dumb animals and learn a good lesson in this regard. The cat in her spare time plays with her kittens; not so much to amuse as to develop them. The same is true of birds. Let the children spend their time out of doors; let them play in the mud until they reach the age of 7 or 8. Then they will become better scholars and make more rapid progress than those who enter the race at an earlier age. I think the municipality owes to every child a good, common school education, and there the responsibility ceases. The high-school system is top-heavy, and it is there, I believe, that the greatest injury is done to the students. They pass through the earlier grades, even through the seventh and eighth, without much trouble, but when it comes to the high school the forcing process begins, and the constant effort to keep up in their studies proves detrimental to many students.

DR. ALBERT E. STERNE, Indianapolis—One important factor that has been overlooked is that of overcrowding, both in our cities and in our schools. It has been claimed that myopia is a cause of mental strain, and *vice versa*, that mental strain causes the myopia. We are losing sight of the fact that the school period is the growing period, or the evolutionary period, both physical and mental, and to my mind certain psychologic or neurotic manifestations are associated with that period. Even the healthy child has certain fancies. The out-and-out psychoses are not common in childhood. None of us see many cases of adolescent insanity; but during this peculiar period erratic or even erotic manifestations are not uncommon.

DR. DANIEL R. BROWER, Chicago—I trust we will go from here prepared to work along the lines specified. I am sure that I have, during the past few years, seen twice as many cases of insanity among adolescents as I formerly saw. A few years ago this matter was brought forcibly to my attention. I had on my clientele the president of the Chicago Board of Education, who was himself an athlete; we had numerous conversations on this subject, and he and I evolved this system, which for a time was put in practice with considerable success: Between each recitation, ten minutes were allowed for rest and exercise, which consisted of light gymnastics or play. Subsequently, objection was made to the plan, and with political changes it was discontinued entirely.

DR. D. L. WILKINSON, Montevallo, Ala.—I will report briefly the results of my investigation during six years of more than 2,000 cases. A necessity for this work arose in my observation in 1898 that at least one girl in every twenty-five in the Alabama Girls' Industrial School was compelled to abandon her work on account of ill health—I may say here that the number of girls who are compelled to abandon college work varies from 4 to at least 50 per cent. I began work along original lines, devising a ledger for the purpose, in which I kept a complete family and personal history of every matriculate. In Ledger 2 I recorded the physical condition at the beginning and close of each session. The former

information was ascertained by my assistant, a young lady, and the latter by the physical culture instructress. The trouble with our educators is that they demand the work of maturity where maturity does not exist. The curriculum is inflexible; pupils are considered as massed entities, no longer as individuals. The teacher endeavors to accomplish a definite amount of work in a limited amount of time, and strives that each succeeding class shall accomplish more than the preceding. My investigations corroborate findings elsewhere, especially those of Dr. Jane Kelley Sabine, Boston. The average age of the girls I examined was 17; the average weight, 113 pounds; the average height, 5 feet 2.1 inches; 75 per cent. suffered from amenorrhea, menorrhea or dysmenorrhea; including leucorrhea and ovarian neuralgia, 90 per cent. were sufferers; 75 per cent. suffered from tonsillitis; 20 per cent. from myopia, hypermetropia or astigmatism; 30 per cent. from constipation; 40 per cent. from headaches. One point Dr. Sabine brought out that the essayists have not touched on: Sixty per cent. of her 2,000 young ladies had to give up work from one to two days each month. My observations did not cover this point. Ten per cent. of our girls come to us with a direct consumptive heredity, i. e., one or both parents died from tuberculosis, or two or more near relatives; 33 1/3 per cent. come with a poor heredity, where one or both parents or two or more near relatives died from diseases which might be regarded as hereditary; five-sixths come with the history of one or more attacks of some severe acute trouble, such as lobar pneumonia, scarlet fever, diphtheria, chronic malarial poisoning, typhoid fever, etc. These points show the origin of troubles prior to college matriculation. I have fixed the average age of puberty in Alabama at the thirteenth to the fourteenth year, 102 girls more menstruating first at 13 than at 14. This would indicate most trouble in the educational system at or about the time when the girls are prepared for college. In the East, I believe that the severest strain is placed on young women before menstruation begins; in the South it is subsequent and therefore at a time when the bodily growth demands the blood of the body. The brain is approximately one-forty-fifth of the body weight, and demands practically one-seventh of the blood of the body. Forced education, therefore, at or subsequent to the time of puberty withdraws blood which is demanded by the growing uterus and adnexa, and results in an undeveloped uterus and an imperfect discharge of the uterine functions. This forced education, too, leads to flabby muscular development, nervous irritation and an increase in neurasthenia, chorea, hysteria, anemia, cardiopathies, and a total breakdown. Pupils in the school referred to work on an average, mentally, of twelve hours, but our school is better than many others, because every pupil is required to carry at least two industrial branches. Now, as to the remedy, educate the teachers to seeing the necessity of the pupils for more rest, interspersed with suitable exercise. Educate the pupils as to the importance of the subject, and in a few generations you will have the parents educated to the point that they will demand a rational plan of education for their children. In Alabama we hope soon to forward to all superintendents of schools and teachers in the state, through the State Board of Health, a circular calling attention to such defects as exist, and requesting the co-operation of the teaching profession in the removal of these difficulties. We are preparing to give special gymnastics in our school to those with developmental defects, and to limit their studies and regulate their habits. I propose to put a circular in each girl's hand, telling her what she may do to develop herself while in school, and what she should do if there is a tendency to any particular trouble. I call your attention to the work now being done in Boston, Chicago, Washington and elsewhere under many able men. I have a third article on this subject now in press, and will be glad to furnish a copy on application.

Dr. Wharton Sinkler, Philadelphia—In the majority of cases very little care is taken of children outside of school hours. The parents are usually occupied with their own affairs, and most of them are untrained in the proper bringing up of children, and so the latter have their own way most of the time. In our large northern cities, during the winter months, the days are so short that the children can not spend many hours out of doors, and must remain in badly lighted, badly ventilated rooms. Any one who sees many of these children at the neurology clinics will find that their home life is anything but what it should be. They are permitted to drink tea and coffee, even to excess; they are overfed with sweets and their time is not profitably employed. We should bear in mind that fault rests not only with teachers but with parents.

Dr. D. I. Wolfstein, Cincinnati—There is no particular danger to the growing child as the result of overwork. We need no better illustration of that than the methods of training children in Germany. A graduate of the ordinary German gymnasium course at 16 has received as complete and strenuous an education as a student in his first or second year at Harvard. To enable a German student to complete his service in the army in one year he must pass an exceedingly difficult examination, and when he presents himself for this examination he can not be regarded as a victim of nervous debility. The reason for this is that the Germans are firm believers in combining intellectual work with physical training. In their numerous *Turn-Vereins* the education of the muscles keeps pace with the education of the mind in the schools. The average country boy learns quicker than the city boy and makes more rapid progress in his studies because he has had the advantage of muscular training and plenty of outdoor exercise.

Dr. A. J. Pressey, Cleveland, Ohio—There is one individual who has not been censured by any of the speakers, and who I believe is responsible for a great many of the drawbacks of our public school system: He is the superintendent. He has usually obtained his position through political preferment, and feels that he must do something for the school, which usually consists in making some addition to the curriculum. Instead of making the work of the children lighter, he usually adds to it with the idea that this will add to his popularity. Another objection to the public school system is that the rules are too inflexible and ironclad. Both of my children were deprived of the benefits of graduating from our high school because they were not strong enough to endure the required amount of work in the prescribed time. If they could have taken a year or two longer to have performed the same labor they could have accomplished it without harm to themselves.

I do not think eyestrain is as much the fault of the school room as it is of the environment. In the city the eye does not get the freedom that it does in the country; there are too many brick walls in the way, which prevent us from using our eyes as God intended them to be used. I do not know whether that theory is correct, but I believe it has much to do with the fact that wearing glasses is very common among city children and comparatively infrequent among children in the country. I do not know how a remedy could be offered for this.

Dr. C. C. Hersman, Pittsburg, Pa.—If we all lived in the country the subject would probably not have arisen. Among savage races the survival of the fittest was the rule of life, but in civilized countries the weakling is taken care of and brought up. The appointment of medical school inspectors is a step in the right direction, but they usually owe their position to political influence and serve their masters rather than the public. The average kindergarten I regard as an abomination. Very young children are sent there to get them out of their parents' way, and the mental condition of the child is developed far ahead of the physical, if the child is inclined to be top-heavy. Such a method of training can only do injury. If I were the father of as many children as old Priam I would not send any of them to school before they were 7 or 8 years old. I have seen children who were not sent to school until they were 8 years old, and within three years they were up to and sometimes far in advance of those who had started at the age of 5 or 6.

Dr. E. T. Shelley, Atchison, Kan.—A great deal of harm that is attributed to school life should rightly be laid to

faulty home life. Parents need education as much as teachers. One element of harm, especially in our smaller cities, is the music lesson fad. After returning from school, worn out and nervous, the girl must take her music lesson. After she has attained a certain degree of proficiency the ambitious music teacher has a public recital where the younger pupils, in a fright and nervous strain, fumble over the keyboard of a piano to the evident delight of foolish and fatuous parents. Another real evil is, I believe, the system of inelastic grading prevalent in nearly all city schools, where young children of greatly varying mental capacity and development are forced into that unyielding mold called a school grade. Country schools are much less prone to this evil, and the result is that it is the usual thing, in my very limited observation, to find country children, from 8 to 12 years of age, from a half year to a year ahead of town children in their school work, notwithstanding the shorter school term of the country school. At all events, on moving to town they are admitted into relatively higher grades than town children of the same age occupy. Is this due to the fact that they have escaped the stunting effects of an inelastic school curriculum?

DR. J. H. MCBRIDE, Pasadena, Cal.—One of the worst features of our public schools is the forced inactivity of the pupils. It is not only injurious to health, but is absolutely deadening to the mind. There are two very interesting books on education that every physician and teacher should read. One is by Prof. William James, "Talks to Teachers on Psychology and Life Ideals." The other is by Prof. Hanford Henderson on "Education and the Larger Life." I wish a committee might be appointed to investigate the subject of the health of school children.

DR. H. T. PATRICK, Chicago—The average physician is shamefully neglectful of his duty in the instruction of parents and the guidance of children. He treats measles and other infantile ailments with enthusiasm and patience, or at least with submission, and has an insatiable appetite for fractures and operations, but when it comes to getting the child's parents into a corner and telling them what they must do and must not do, he puts on his hat instead and walks out of the house. He is not willing to risk the disfavor of his patients by telling them frankly what he thinks. The German system of mental and physical training is in some respects far superior to ours, but conditions of the two countries are not the same. I am convinced that in Germany they do not begin to live the strenuous life that we do, particularly as regards children and young people. The opportunities for advancement and attainment in this country are so great as to place a very tempting bait before every individual, and this has its influence on the education of children. Every young man who starts in business looks forward to becoming a Napoleon of finance, and every girl who gets into long dresses looks forward to being a brilliant figure in society or in whatever direction her ambition leads her. There is too little of the placid content that we see in Germany, and this has a great influence on the effects of our education. Charcot long ago said that children do not have neurasthenia, and this is true if the child is left to follow his or her inclinations. But children are not left alone; they are given a stiff curriculum in school and music lessons outside; they must take part in recitals; they must know something of French, German and Italian, paint a little and decorate china. They must do everything that their friends do, and do it all a little better. These accomplishments are not only tolerated, but even encouraged by the parents, and the teacher naturally tries to turn out the highest possible product. The greatest sin is committed by the medical man who neglects or purposely avoids his full duty in this matter.

DR. WILLIAM S. LINDSAY, Topeka—We should not attempt to correct all this by changing the present methods of the management of children. The overwork of the parents is shown in the condition of the children. I feel that we have something to do in looking after our own habits and method of living, in order that the coming generation may be better prepared for the strenuous conditions with which they will have to contend.

DR. F. W. LANGDON, Cincinnati—We once had in Cincinnati an old physician, somewhat eccentric, but very successful in his profession, and possessing good, sound common sense. His two daughters, at least one of whom was inclined to be neurotic, on returning from their select private school one day, informed their father that they were to have several new studies added to their curriculum. As they were already overburdened in this respect, the physician called on the preceptress and told her rather forcibly what he thought about it. "Well," she said, "you desire your daughter to have an education?" "Yes, Madame," he responded. "But I also desire her to have some legs and lungs and stomach." Every psychosis is preceded by a neurosis, and we should not wait for a psychosis to develop or threaten before we adopt our preventive measures. The average new school superintendent, who is brought to the city or town to take charge of the schools, thinks he must add something to the curriculum. He never thinks of taking anything off. The ordinary school curriculum is top-heavy and too extensive and as a consequence the hours of study are too long. There is too much memorizing and not enough teaching. The student is not taught to think, but to cram, and that is the fault of the teacher. The remedies I have to suggest are these: 1. Reduce the curriculum in regard to the special, abstract studies. 2. Shorten the hours. 3. Increase the number of teachers in proportion to the number of pupils. A teacher can not take care of 50, 75 or 100 pupils and do justice to them all. We must adapt the curriculum and hours to the ability of the average pupil, and not to that of the highest examples of intellectual development. No one is so quick to listen to the views of public opinion as the politician, and if he does not act as we think he should in this matter, it is because we have been a little tardy in expressing our opinions.

DR. F. SAVARY PEARCE, Philadelphia—The physician too often limits himself to actual medical treatment, and rarely takes the time to give any instructions to parents regarding the value of preventive or hygienic measures. He does not feel called on to take any active part in the discussion of these subjects at public meetings; a very important matter. The consensus of opinion of those who have taken part in this discussion has been clearly enough that the educational methods in this country are open to great improvement, and I trust that some effective measures will be taken by this Section so that the views held can be placed before the public in a brief and succinct form. We hope to be students to our dying day, but the bud must not be neglected.

DR. WILLIAM J. HERDMAN, Ann Arbor, Mich.—This is a topic that has been in the heart of every earnest physician in this country. This is the age of preventive medicine. Our duty is not alone to those who are here, but to those who are to be here in the future. We as neurologists, more than any other class of physicians, fully recognize that a large percentage of the abnormalities with which we have to deal can not be helped by to-day's methods. In many of these cases we can simply give temporary relief, but we know that if we do our full duty to-day we must strive to stem this constant current of disease. The other day we listened to Dr. Crother's excellent paper on the pathologic effects of alcohol. Each one of us, in his daily work, sees the injurious effects of alcoholic stimulants. The neurologist recognizes the utter hopelessness of dealing with chronic alcoholism. We know that it is one of the most fertile causes of disease; that it is filling our almshouses, insane asylums and prisons, and daily increasing the number of feeble-minded, and still, what have we done, as physicians, to declare that fact to the public? We as physicians also know that the prevalence of syphilis is responsible for a very large percentage of diseases that come before us every day. How can you help a case of tabes in its third stage? We must go further back and try to reach the root of the evil. Have we performed our full duty to the public or to posterity if we fail to make ourselves heard on these subjects? I believe we do not sufficiently recognize the fact that we are fulfilling a very small share of our duties in connection with preventive medicine. We all recognize the

fact that education is an important factor in the future welfare of mankind, and we also recognize that neuroses and psychoses may result from faulty school methods, but we are not yet in a position to take definite action regarding the matter. We have not collated the knowledge we have on the subject, and we are not in a position to say that this or that is the best method to adopt. That is something that must be done deliberately and scientifically, and our conclusions must rest on a broad, sound foundation.

THE VOLUNTARY AND INVOLUNTARY BRAIN CENTERS CONTROLLING THE OCULAR MUSCLES.*

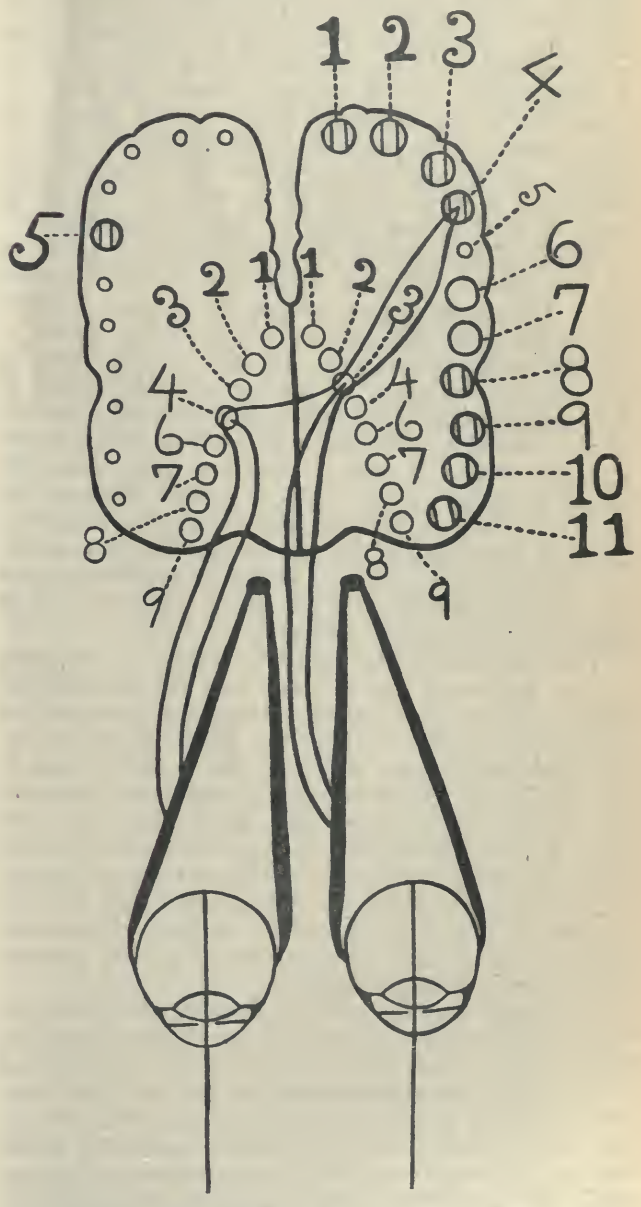
G. C. SAVAGE, M.D.

Professor of Ophthalmology in the Medical Department of Vanderbilt University.

NASHVILLE, TENN.

There are two groups of brain centers for controlling the movements of the eyes. One group is found in the cortex, and consists of nine distinct centers. In this group are two more centers, making eleven in all, but these two are connected with muscles within the eye, viz.: the Müller muscle in the ciliary body and the sphincter of the iris, and will not be specifically studied in this paper. The second group is located at the base of the brain, and consists of twelve distinct centers. In this group are four more centers, making sixteen in all, but these four are connected with the muscles within the globe already mentioned, hence they will be passed without further mention.

THE CORTICAL GROUP.



Experimentation and pathology both have given evidence of the existence of the cortical centers. Experimenters on the lower animals have not yet found all the cortical centers to be studied in this paper; nor have any of these centers been very definitely located. These experiments teach us that some of these centers are in the anterior part of the motor area, not far from the outer extremity of the crucial sulcus.[1] Future experimenters, doubtless, will be able to find them all and give to each an exact location.

An irritative disease of the cortex, in the motor area, has caused the two eyes to turn spasmodically toward the opposite side; and destructive disease in the same part has caused a paralytic turning of the two eyes toward the corresponding side. Thus has pathology located both the fourth and fifth conjugate centers in the cortex.

Our chief evidence as to the existence of the cortical centers is physiology—the action of the muscles in moving the eyes. Each of the nine cortical centers is connected with two muscles, one belonging to each eye, thus showing that some of the fibers of each of the motor nerves cross over to the opposite side of the brain. This decussation, it must be confessed, has not yet been fully demonstrated anatomically; but this demonstration will come soon. Cunningham, in his anatomy, teaches more about the decussation of fibers of the motor nerves of the eyes than any one else whom I have consulted, but his interpretation of the crossing is erroneous.

Since the arrangement and exact location of the cortical centers controlling the ocular muscles are unknown, nothing but a schematic representation of them can be made in a cut. The schematic plan is also followed in the cut, in the attempt to show the basal centers, notwithstanding the arrangement and location of these are fairly well understood.

The centers controlling the ocular muscles, whether cortical or basal, are under the mastery of the mind. Volition presides over all the cortical centers that are connected with the recti muscles and over two of the centers connected with the obliques, while the other two centers connected with the obliques are presided over by the fusion faculty of the mind. The basal centers

are all under the mastery of the fusion faculty. Those centers under the control of volition are represented in the cut by circles crossed with parallel lines, while those under the control of the fusion faculty are represented by circles only. All these centers are numbered arbitrarily, but in such a way as to lead to as little confusion as possible. The cortical centers are numbered from 1 to 9 on each side of the brain; but, since only half of these centers are needed for effecting the conjugate movements of the eyes, the other half are supposed to be inactive. The active nine, eight on one side and one on the other, are represented by large circles, while

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

1. See Stewart's Physiology, 4th ed., p. 473.

the inactive nine are represented by small circles. The basal centers on each side of the median plane are all represented as equal in size, for the reason that each must stand ready for action whenever an emergency arises.

The first cortical center is connected with two superior recti by means of two bundles of fibers, both bundles passing through the first basal center on the same side, the one to be distributed to the superior rectus of the corresponding eye, while the other bundle of fibers crosses to the first basal center on the opposite side, thence on to be distributed to the superior rectus of the other eye. Throughout their entire course these fibers are insulated, even in that part which passes through a basal center. When volition unlocks the first conjugate center the discharged neuricity goes only to the two superior recti, and in equal quantities. If the tonicity of the one muscle equals the tonicity of the other, the upward rotation of the one eye will be the same in rapidity and extent as that of the other.

The second conjugate center is connected by means of two bundles of nerve fibers with the two inferior recti. Both bundles pass through the second basal center on the same side, the one to the inferior rectus of the corresponding eye, while the other bundle crosses to the second basal center on the opposite side, thence to the inferior rectus of the other eye. What has been said of the insulation of the nerve fibers going from the first conjugate center is true of the fibers going from the second conjugate center. When volition liberates the neuricity in the second conjugate center, it is conducted in equal quantities, by the two bundles of fibers, to the two inferior recti. If the tonicity of these muscles is the same, the two eyes will be rotated downward equally rapidly and to the same extent.

The third conjugate center is connected by means of two bundles of nerve fibers with the two internal recti, both bundles of fibers passing through the third basal center on the same side, the one to the internus of the corresponding eye, while the other bundle crosses to the third basal center on the opposite side, thence to the internus of the other eye. These fibers are, likewise, perfectly insulated. To the liberated and transmitted neuricity the two interni always respond equally in time and extent, for the tonicity of the one internus is practically always equal to the tonicity of the other internus. The third conjugate center is very properly called the convergence center.

The fourth conjugate center directs and controls the right sweep of the eyes, and is therefore connected by means of two bundles of nerve fibers with the externus of the right eye and internus of the left eye. Both bundles of fibers from the fourth conjugate center pass through the third basal center on the same side, thence one bundle goes to the internus of the corresponding eye, while the other bundle crosses to the fourth basal center on the opposite side, thence to the externus of the other eye. This arrangement of the connecting fibers is shown in the cut, and will be referred to again. When volition liberates the neuricity in this center, it is conducted by the two bundles of fibers, in equal quantities, to the two muscles, and if the tonicity of one muscle is equal to the tonicity of the other, the two eyes will move to the right in perfect harmony.

The fifth conjugate center is connected by two bundles of nerve fibers with the externus of the left eye and internus of the right. As shown in the cut, the active fifth center is probably not on the same side of the brain as the other active centers. The two bundles of fibers from the fifth conjugate center pass through the third basal center on the same side, thence the one bundle goes to the internus of the corresponding eye, while the other bundle crosses to the fourth basal center on the opposite side, thence to the externus of the other eye. In effecting the left sweep of the eyes, these muscles, under normal conditions, will respond in perfect harmony to the neuricity set free by the fifth conjugate center.

The five conjugate centers thus far studied are alike in several respects: (1) They are each under the control of volition; (2) each is connected with two muscles, the one belonging to the one eye and the other belonging to the other eye, and the connecting fibers are insulated everywhere; (3) the neuricity liberated by any one center goes in equal quantities to each of the two muscles; (4) they are all connected with the recti muscles; (5) they act in the same way whether there is orthophoria or heterophoria; in other words, these conjugate centers under the control of volition never concern themselves with the correction of heterophoria in any of its forms.

The sixth and seventh conjugate centers are under the control of the fusion faculty of the mind, hence these centers in the cut are not crossed by parallel lines as are the volitional centers.

The sixth conjugate center is connected by two bundles of nerve fibers with the two superior obliques, both bundles going through the sixth basal center of the same side, the one to the superior oblique of the corresponding eye, while the other bundle crosses to the sixth basal center on the opposite side, thence to the superior oblique of the other eye. This center acts in association with the second conjugate center. When the eyes are rotated downward by the second conjugate center, the vertical axes would be made to diverge above, a condition that would cause diplopia. The fusion faculty prevents this diplopia by exciting the sixth conjugate center, the neuricity from which is conducted in equal quantities to the superior obliques. These muscles responding prevent the divergence of the vertical axes, thus maintaining binocular vision; and they also help the inferior recti to rotate the eyes downward.

The seventh conjugate center is connected by two bundles of nerve fibers with the two inferior obliques. The two bundles of fibers pass through the seventh basal center on the same side, the one bundle to the inferior oblique of the corresponding eye, while the other bundle of fibers crosses to the seventh basal center on the opposite side, thence to the inferior oblique of the other eye. This center acts in association with the first conjugate center. When the eyes are rotated upward by the first conjugate center sending its neuricity to the two superior recti, the vertical axes would be made to converge above, a condition that would cause diplopia. To prevent this torsioning and its consequent diplopia, the fusion faculty causes the seventh conjugate center to discharge its neuricity, which is conducted in equal quantities to the two inferior obliques. These muscles responding prevent the torsioning of the eyes, thus maintaining binocular single vision; and they also help the superior recti to elevate the eyes.

The sixth and seventh conjugate centers not only act in association with the second and first conjugate centers, respectively, but, being under the mastery of the fusion faculty, they must also correct a cyclophoria which is equal in the two eyes, and must produce compensating cyclotropia in cases of oblique astigmatism

with equal, but opposite, distortion of the images in the two eyes.

Oblique rotations of the eyes can not be accomplished without creating a tendency on the part of both eyes to tort, but always to the same extent and in the same direction. If this torsioning occurred there would be no diplopia, for the vertical axes of the eyes would still be parallel, but there would be an apparent wheel-like motion of all objects in space, in the direction opposite to the torsioning. To prevent this torsioning in oblique rotations, there are two more conjugate centers, the eighth and ninth, certainly not under the control of the fusion faculty, but probably under the control of volition in the interest of visual judgments.

The eighth conjugate center is connected by means of two bundles of nerve fibers with the superior oblique of the right eye, and the inferior oblique of the left eye. The two bundles pass through the seventh basal center on the same side, thence one bundle goes to the inferior oblique of the corresponding eye, while the other bundle crosses to the sixth basal center on the opposite side, thence to the right superior oblique. This center is excited into action only when the rotation is obliquely up and to the right, which is accomplished by the associated action of the first and fourth conjugate centers, or down and to the left, which is effected by the associated action of the second and fifth conjugate centers. In either case the torsioning tendency of both eyes would be to the right. In these rotations the eighth conjugate center sends neuricity in equal quantities to the right superior oblique and the left inferior oblique, the contractions of which maintain the parallelism between the vertical axes and the median plane of the head, thus preventing the wheel-like motion that objects otherwise would have.

The ninth conjugate center is connected by means of two bundles of nerve fibers with the superior oblique of the left eye and the inferior oblique of the right eye. These two bundles from the ninth center pass through the sixth basal center on the same side, the one bundle to the left superior oblique, while the other bundle crosses to the seventh basal center on the opposite side to the right inferior oblique. This center is excited into action only when the two eyes are rotated obliquely up and to the left, which is accomplished by the associated action of the first and fifth conjugate centers, or down and to the right, which is effected by the associated action of the second and fourth conjugate centers. In either case the torsioning tendency would be to the left. To prevent the torsioning, and consequent wheel-like motion of objects, the ninth conjugate center calls into action the left superior oblique and the right inferior oblique, so as to keep the vertical axes parallel with the median plane of the head.

Like the five centers connected with the recti muscles, these two centers connected with the obliques perform the same kind of work whether there is orthophoria or heterophoria. No attempt is ever made by these two centers to correct any form of heterophoria.

In lateral rotation of the eyes only one conjugate center is excited; in vertical rotations there is associated action of two conjugate centers; in all oblique rotations there is associated action of three conjugate centers. During waking hours, consciously or unconsciously the point of view is changed frequently, and thus brief periods of rest come to all conjugate centers. It is doubtful if these centers ever excite nervous symptoms, whether the eyes be orthophoric or heterophoric. It is true, however, that fixedness of gaze for a prolonged period will cause trouble.

BASAL CENTERS.

The basal centers differ in many respects from the cortical centers. There is one basal center for each ocular muscle, and each center can act only on one muscle. The basal centers are all under the control of the fusion faculty of the mind, and none of them are ever called on to discharge neuricity unless a condition exists that would cause diplopia. In emmetropia and orthophoria the basal centers never have any work to do, and, therefore, could never cause symptoms. In ametropia there is always an associated pseudoheterophoria for the correction of which there would be unremitting excitation of one or more of the basal centers. In many of these cases the pseudoheterophoria is more serious than the causative ametropia, but the correction of the latter means the cure of the former, provided there is no underlying intrinsic heterophoria. When ametropia is complicated with intrinsic heterophoria, what to do for the former becomes a question not to be answered in this paper.

Badly adjusted spheres or cylinders always give a tendency toward diplopia, for the correction of which one or more centers under the control of the fusion faculty must be continuously active, symptoms more or less severe always resulting. Prisms excite the basal centers only.

The final object of this paper is the study of the basal centers in their relationship to intrinsic heterophoria. In intrinsic heterophoria, the two muscles of a pair have not the same tonicity, and diplopia would always result if it were not for the existence of the basal centers; for, as already shown, at least seven of the nine cortical centers have nothing to do with the correcting of any form of heterophoria.

The basal centers connected with the ocular muscles are twelve in number, and all are found in the back part of the floor of the third vertical, in the floor of the aqueduct of Sylvius, and in the anterior part of the floor of the fourth vertical, six lying on either side of the median plane. Cunningham has shown that the fibers cross from the nucleus of the sixth nerve on one side to the nucleus of the third nerve connected with the internus, on the other side (from the fourth basal center to the opposite third basal center). His interpretation of this crossing was that it associated these basal centers in the right and left sweep of the eyes. It is probable that the partial decussation of the fibers of all the motor nerves takes place between the basal centers, but not to unite them in action. The fibers conducting neuricity from a basal center do not cross. These fibers begin in a basal center and end in a muscle on the same side. The crossing fibers simply pass through the basal centers on their way to the cortical or conjugate centers, and doubtless are insulated everywhere.

The basal centers will be spoken of as right and left, and are numbered as follows: The two connected with the two superior recti are right first and left first; the two for the inferior recti are right second and left second; the two for the interni are right third and left third; the two for the externi are the right fourth and the left fourth; the two for the superior obliques are the right sixth and the left sixth, and the two for the inferior obliques are the right seventh and the left seventh. As will be seen, these basal centers are numbered in harmony with the cortical or conjugate centers.

In vertical orthophoria the right and left first centers and the right and left second centers are never called into action for the reason that, in this condition, there is never any tendency to vertical diplopia. In right hyperphoria and left cataphoria, the quantity being small or great, with the object in the horizontal plane, the right second center and the left first center are constantly supplying neuricity to their respective muscles, under the guiding influence of the fusion faculty, so as to prevent diplopia.

In lateral orthophoria, the right and left third centers and the right and left fourth centers are in repose at all times, for in such a condition there is no tendency to lateral diplopia. In esophoria, when the object is in the vertical plane, the right and left fourth centers are in a constant state of activity to prevent diplopia that would result if the visual axes were allowed to cross between the object and observer. In exophoria, when the object is in the vertical plane, the right and left third centers are continually supplying neuricity to their respective interni so as to prevent the diplopia that would result if the visual axes were allowed to intersect beyond the object.

In orthophoria of the obliques, and when there is no oblique astigmatism, the right and left sixth and seventh basal centers never have anything to do. Plus cyclophoria equal in the two eyes is doubtless corrected by the sixth conjugate center, but when the right superior oblique is weaker than the left, the work of the sixth conjugate center is supplemented by excitation of the right sixth basal center, the weaker muscle needing a greater quantity of neuricity than is supplied by the conjugate center. Minus cyclophoria equal in the two eyes is doubtless corrected by the seventh conjugate center, but if the left inferior oblique is weaker than the right, the left seventh basal center must furnish additional neuricity to this weaker muscle.

The study of the verting of heterophoric eyes is not without interest. If there is right hyperphoria, and the eyes are to be rotated upward, the second conjugate center and the right and left second basal centers withhold all nerve influence from the two inferior recti; but the first conjugate center calls into action the two superior recti, and there is associated action of the seventh conjugate center. The tonicity of the superior rectus of the right eye being greater than that of the left, the former, under the influence of a given quantity of neuricity, would rotate its eye more rapidly than the left would be rotated. To prevent the diplopia that would result the fusion faculty causes the left first basal center to send additional neuricity to the left (the weaker) superior rectus, and thus the two eyes are made to rotate upward in perfect harmony. If the same eyes are to be rotated downward, the first conjugate and the right and left first basal centers become inactive, while the second conjugate center, and, in association, the sixth conjugate center, send neuricity to their respective muscles and both eyes are rotated downward; but since the tonicity of the left inferior rectus is greater than that of the right, the left eye would rotate more rapidly. To prevent the diplopia that would result, the fusion faculty causes the right second basal center to send additional neuricity to the right (weaker) inferior rectus, so that the two eyes may rotate in harmony.

The nerve fiber connections between the cortical and basal centers and the muscles that effect the right sweep of the eyes, are shown in the cut. All neuricity is withheld from the left externus and right internus, when the right rotation is to be effected. In exophoria, the fourth conjugate center, under the guidance of volition, will send neuricity down the two bundles of nerve fibers, in equal quantities, to the right externus and the left internus; but since the tonicity of the former is greater than the tonicity of the latter, the right eye would rotate more rapidly than the left, and there would be diplopia. The fusion faculty being on its guard, calls into action the left third basal center, the neuricity from which supplements the neuricity sent from the fourth conjugate center to the left internus, and thus the left eye is made to move in perfect harmony with the right, and there is no diplopia. If these eyes were esophoric, the right eye would move more slowly than the left, under the stimulus of the fourth conjugate center, and there would be diplopia. To prevent this the right fourth basal center must send supplemental neuricity to the weak right externus so as to make it act in harmony with the strong left internus.

In the same manner as above, every possible rotation of heterophoric eyes could be studied, showing exactly the basal centers that would be called into action to prevent diplopia. But the further study would only do what has already been done; that is, establish the fact that the brain centers under the control of volition have nothing to do with the correction of heterophoria, but that this work is accomplished by those centers under the control of the fusion faculty of the mind.

From the foregoing study of the voluntary and involuntary brain centers controlling the ocular muscles, the logical conclusion concerning heterophoric conditions is as follows: These errors should be corrected by non-surgical or surgical means, so as to give to those brain centers which are under the control of the fusion faculty that rest from all excitation which they have in orthophoria. This can be done only by making the tonicity of the one muscle equal to the tonicity of the other muscle of any pair.

DISCUSSION.

DR. EDWARD JACKSON, Denver—Is not the scheme rendered more elaborate than is necessary by supposing a series of centers that are to act only in emergencies? Would not a single center, able to vary its action, be sufficient?

DR. G. C. SAVAGE—I do not want any one to overlook the experiments that have been done on animals, and what the pathology has shown. Experimenters and observers have much to do yet. I would recommend the purchase of Cunningham's work on anatomy, in which the results of careful dissections have been recorded. It is possible to study every possible sweep of the eye and every possible form of heterophoria in the line of my paper.

The Unselfishness of Physicians.—There is a disposition often to scoff at the code of ethics by which doctors of medicine are governed—at the rule which brands as a quack any practitioner who keeps for his own exclusive use and profit any discovery he may make of a curative agent. Yet there is no other profession which gives more for nothing to the public, and whose giving in that respect is absolutely without selfish motive. This is illustrated by a recent statement to the effect that the revenues of the medical profession in recent years have practically been cut in two by the hygienic reforms which have been brought about by the efforts of the doctors alone. That statement is well within the realm of truth. Medical science is constantly striving to make it possible for the human race to get along with less medical treatment. Not only are the efforts of investigators directed to the discovery of new and more effective remedies for disease, but to discover means of preventing the spread and even the inception of disease. Broadly speaking, the doctors are working continually to deprive themselves of occupation and revenue.—*Cleveland Leader.*

RETROVERSION OF THE UTERUS.

A CLINICAL STUDY OF THE COMPLICATIONS, SYMPTOMS AND TREATMENT.*

L. H. DUNNING, M.D.

Professor of Diseases of Women, Medical College of Indiana.

INDIANAPOLIS.

The writer has found 112 recorded cases of retroversion of the uterus examined by him in his office practice from June 10, 1900, to Jan. 9, 1903. An accurate and fairly comprehensive record of these cases has been kept in his case book. Such essential points as were omitted in the original entry have been looked up and duly entered.

A clinical study of these records was begun with the hope that the findings might be helpful in furnishing the writer with some positive indications for treatment of future cases. He has found the study profitable and herewith submits his findings, together with such remarks and conclusions as present themselves to him.

Unfortunately, forty-three of the 112 cases whose histories are recorded were seen by the writer but once or twice, so he can say nothing regarding their subsequent course. Fifty-six cases in all were treated by the writer. A brief outline of the histories of these cases is included in this paper. The whole number (112) were tabulated and each case studied in detail. But eight cases were found in which retroversion alone existed and in six cases only in which a single complication was endometritis; in other words, in 85 per cent. of cases retroversion was but one of the three or more pathologic conditions present in each case. In many instances other lesions present were of more grave import than was the retroversion, yet, inasmuch as retroversion was present in every instance, viz., in 112 cases, while the other most frequent lesion was present only forty-eight times, it is fair to treat other lesions as complications of retroversion. The following complications were found to be present, viz.:

Prolapsus of one or both ovaries	48 cases.
Endometritis	32 cases.
Laceration of the cervix uteri	27 cases.
Prolapsus of the uterus	17 cases.
Adhesions of the uterus or ovaries	15 cases.
Laceration of the perineum	8 cases.
Movable kidney	8 cases.
Chronic inflammation of the ovaries without displacement	9 cases.

There were a few cases in which the following pathologic lesions were present: Retroflexion, chronic appendicitis, hyperplasia, salpingitis, cystitis, colitis, rectocele and cystocele. Relaxation of the abdominal walls was frequently encountered, but not accurately recorded.

We believe our records do not show truly the frequency of retroflexion as a complication. I hope to be able at some future time to say something more definite on this subject. I believe, too, the records should have been more explicit in stating other morbid conditions found in the displaced ovaries.

We all know the chronically prolapsed ovary is frequently also a chronically inflamed ovary, and this fact must be taken into the reckoning in the treatment of all cases of retroversion of the uterus with prolapsed ovary.

Regarding prolapsus of the ovary, the following findings were noted, viz.:

There was prolapsus in the right ovary in	17 cases.
Prolapsus of the left ovary in	12 cases.
Prolapsus of both ovaries in	9 cases.
Prolapsus of one ovary, side not stated, in	10 cases.

In 42.7 per cent. of cases of retroversion of the uterus there is prolapsus of one or both ovaries. In the list sixty-six women had borne children. Of these, thirty-four, or 51 per cent., had prolapsus of one or both ovaries, while of the forty-six women who had not borne children there were 14, or 30 per cent., who had prolapsus of one or both ovaries. It is thus seen that child-bearing predisposes to retroversion with prolapsus of the ovary.

The next most frequent complication was laceration of the cervix uteri, which occurred in twenty-seven cases (24.1 per cent.) and which, when present, was frequently associated with endometritis and subinvolution of the uterus. In every case but one of laceration of the cervix there are other lesions also complicating the retroversion.

There was prolapsus of the right kidney in seven cases and of both kidneys in one, the eighth case. Not infrequently a pendulous abdomen and general enteroptosis were also found associated here. It is surprising to find so few cases of laceration of the perineum recorded, yet I am convinced that my observations were accurate on this point.

There are recorded seventeen cases of prolapsus of the uterus. In most instances the prolapsus of the uterus was of the first degree only, and none of extreme prolapsus. This displacement seemed to exercise very little influence in modifying the symptoms produced by the other complications.

Adhesions of the uterus were noted in fifteen cases. For the most part these adhesions were slight, but when present, except in the three acute cases, they were considered as indications for operative intervention. Gentle massage and manipulation of the uterus followed by tampons was found beneficial in two cases. It must be remembered in this connection that these cases occurred in private practice and among well-to-do and wealthy people, so there were few cases of previous gonorrheal infection. The writer's experience in free dispensary and charity hospital practice is quite different. There he finds a much larger per cent. of inflammatory cases, both acute and chronic, due to gonorrheal infection or infection following miscarriage or abortion.

A most interesting study is that of the symptoms present. Backache and bearing down in pelvis is the chief complaint in uncomplicated retroversion, being found present in seven cases, while painful menstruation occurred in three cases only.

A somewhat different train of symptoms appears when the retroversion is accompanied by endometritis. In this class it is found that profuse and painful menstruation, burning through the uterus, marked nervousness and soreness through the uterus and general weakness are the chief symptoms. There was also backache in the majority of cases.

If we study the cases collectively we find pain as the one symptom which is almost universally present in this disease with such a variety of complications. It is recorded as being present in 83, or 74 per cent., of cases. This statement of pain includes painful menstruation in forty-one (36 per cent.) cases; backache, forty (45 per cent.) cases; pain in the inguinal regions and head, and in inflamed and prolapsed ovary, and often pain extending down the limb. In the long and varied train of symptoms recorded appear profuse menstruation, gastric disorders, headache, distressing nervousness, wake-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newmar and J. H. Carstens.

fulness and general weakness. All the women in the complicated cases were invalids in a greater or less degree.

TREATMENT OF CASES.

Of these 112 cases, 56 were under observation and treatment sufficiently long to enable me to speak with positiveness regarding results. A brief history of each case is presented, excepting the five cases in which there were neoplasms causing the displacements. There were two of ovarian tumors and three uterine fibroma. These were operated on, the tumors removed and the displacements cured. The uterus was removed by the supravaginal method in the fibroid tumor cases and in the ovarian tumor cases the retroversion and prolapsus were found cured on the patient's recovery from the operation.

Thirty-five cases were treated by non-operative methods. By "non-operative methods," as employed here, we mean posture, tampons, pessary, topical applications and internal medicines. In a few of the cases a curettage was done for the cure of endometritis, as, for instance, in Group 1, Case 12, in which there was marked endometritis and erosion, a curettage was done and a pessary employed for one and a half years. The patient was cured.

In some instances topical applications were made to the interior of the uterus for the cure of the endometritis, with successful results, as in Case 61, Group 1.

In one instance curettage, trachelorrhaphy and perineorrhaphy were done as in Case 64, Group 1. Here rest in bed and postures following the operation resulted in a cure of the patient. This case is included among non-operative cases.

The internal medicines employed were of more than incidental value in assisting in bringing about cure and relief. They consisted of laxatives when needed, cascara and rhubarb being preferred in cases of obstinate constipation. Occasional doses of salines were used in all recent cases and when there were evidences of chronic pelvic congestion. Hydrochloric acid and nux vomica and a carefully regulated diet were chiefly relied on in gastric disorders; bitter tonics and iron in suitable cases were prescribed.

Sometimes, when there was a large, tender uterus and prolapsed ovary, rest in bed with hot douches, an occasional saline, bitter tonics, general massage, passive movements and the knee-chest position were all employed, and brought to the patient great benefits. These cases are listed in the group as being benefited. They were not cured, but the patients were rescued from invalidism and were enabled to again take up and enjoy the duties of life.

The cases treated are divided into groups, a very brief outline history of each case given, with results and with brief remarks under each group. For the purpose of aiding those who care to study these cases, this will be found a convenient arrangement. It has been a laborious task for the writer to gather these histories and results, and to properly arrange and group them; but he has in the study incident to the work found himself abundantly rewarded.

The word cure here is applied in a positive sense in relation to the retroversion, but in a somewhat relative sense in reference to the complications; for instance, a case reported cured was well of the displacement at the end of the treatment and at the time of subsequent examination, and so were the complications immediately associated with or dependent on the displacement; whereas complications not so immediately associated with the displacement were not cured, as, for instance, if the patient was well of all diseases except cystitis, or colitis, she was reported as cured.

When benefits result from the treatment, the extent of the benefit is indicated. It must be evident to any one familiar with the numerous abnormal conditions we are considering under the head of retroversion of the uterus that the various morbid manifestations we call symptoms have developed gradually and have made, if they have existed long, a deep and more or less lasting impression on the system and life of the patient. I have already stated that pain is the most constant symptom, and my experience in treating these and many other cases has taught me that it is the most persistent. The three symptoms most prone to persist are painful menstruation, pain in the inguinal region and nervousness. So frequently do these symptoms remain after all other evidences of disease of the structures under consideration have disappeared that we are compelled to acknowledge that the term cure must be employed in a restricted sense. A woman who is found an invalid, and so far restored to health that she is able to again take up the duties of her position and discharge them with alacrity without suffering more than an occasional attack of pain, discomfort or nervousness, may deem herself cured. Such good results are often effected in treating retroversion of the uterus with its complications both by operative and non-operative treatment.

GROUP I.—TREATED WITH TAMPONS OR PESSARY, INTERNAL MEDICINES AND POSTURE. CURED.

Case 7.—Miss A., aged 21. Retroversion. No complications. Overworked schoolgirl. Backache. Painful menstruation. Displacement of two or three years' standing. Rest. Internal medication. Pessary. Cure of displacement in one year. The symptoms disappeared much earlier.

Case 14.—Miss B., aged 21. Retroversion. No complications. Backache. Painful menstruation. Pessary one year. Displacement cured. Symptoms but slight.

Case 54.—Mrs. C. Married two months. Retroversion. No complications. Displacement of some months' standing. Slight cystitis. Tampons, then pessary four months. Cured.

Case 12.—Miss D., aged 28. Retroversion. Slight prolapsus, endometritis and erosion. Curettement and pessary one and a half years. Cured.

Case 61.—Miss E., aged 24. Retroversion. Endometritis, erosion of cervix. Gradual dilatation of cervical canal. Topical applications. Cured endometritis. Pessary worn one year. Displacement cured.

Case 73.—Mrs. F., aged 30. No children. Retroversion, slight. Pelvic congestion. Recent case. Cathartics, restricted diet, internal medicines. Tampons. Cure.

Case 100.—Mrs. G., aged 30. One child seven months old. Retroversion. Subinvolution. Ovarian congestion. Cathartics, internal medicines. Tampons. Cure.

Case 64.—Mrs. H., aged 48. Seven children. Retroversion, first degree. Endometritis, laceration of the cervix and perineum. Curettement, trachelorrhaphy, perineorrhaphy. Rest in bed, posture. Cured.

SUMMARY—EIGHT CASES.

Pessary	5 cases.
Tampons	2 cases.
Plastic operation and rest and posture	1 case.

Of the number cured, it will be observed that they were all, except one (Case 64), young women, and none of the complications relates to injuries to the uterus or disease of the ovaries, except that one of them suffered ovarian congestion and one of laceration of the cervix. This is a most instructive series. It will be observed, too, that an effort was made to cure the endometritis by topical applications and two by curettage, and that the benefit of the knee-chest position was secured.

The pessaries employed were the Albert Smith retroversion, the Thomas-Smith retroversion or the Hodges closed bar retroversion pessary. The patient was placed in the knee-chest position or the exaggerated Sims position, with the head low and the body on the inclined plane. The uterus was then placed in its normal position by finger pressure or by a cotton probang carried behind the uterus and pressed forward and upward. In some instances these manipulations were not efficient, and then recourse was had to the Elliott or Sims repositor. If we were still unsuccessful, we knew we had to deal with adhesions and desisted from further efforts at replacement. Such cases are best treated by operative measures.

The fitting of the pessary is of great importance. The instrument should be neither too long or too short, too narrow or too wide. As a rule, a digital examination will enable one to make a close estimate of the size of the instrument required. After the introduction of the pessary its efficiency should be tested in many ways, as, for instance, by allowing the patient to walk up and down a flight of stairs or step on a chair and down again and then be examined to determine if it is in proper position and is yielding the proper support. If it does not meet all the requirements it should be replaced by one that does. In some instances no pessary will be retained or give the proper support. In such cases, as a rule, tampons, no matter how long employed, will be of little permanent value.

GROUP II.—RETROVERSION TREATED BY TAMPONS. BENEFITED.

CASE 23.—Mrs. A., aged 35. No children. Retroversion, endometritis and slight adhesions. Had pus tube removed some months ago. Tampons and treatment of the erosion. Markedly improved.

CASE 37.—Mrs. B., aged 46. Three children. Recent pelvic inflammation. Retroversion, first degree. Rest, internal treatment and tampons. Marked improvement.

CASE 49.—Mrs. C., aged 56. Three children. Retroversion, senile vaginitis, laceration of cervix. Past menopause. General and local treatment, tampons. Symptomatic cure.

CASE 53.—Mrs. D., aged 35. Two children. Retroversion, laceration of the cervix uteri and laceration of the perineum, slight. Left ovary congested. Tonics, rest, tampons. Improved.

CASE 71.—Mrs. E., aged 24. No children. Retroversion, endometritis and prolapsus of one ovary. Not many symptoms. Rest, posture and internal medication. Improved.

CASE 80.—Mrs. F., aged 39. Four children. Retroversion. little endometritis, prolapsus of both ovaries, dilated colon. Replaced uterus, applied tampons, colonic irrigation. Much improved after one month's treatment.

CASE 93.—Mrs. F., aged 22. No children. Retroversion, prolapsus of uterus and both ovaries. Has had pelvic inflammation. Tonics, alteratives, laxatives and tampons. After three months' treatment much improved. (Recent case.)

CASE 96.—Mrs. G., aged 34. Two children. Extreme retroversion, prolapsus of right ovary, a chronic invalid. Rejected operation. Rest, posture, internal medicines. Tampons. Greatly benefited after three months' treatment.

Three cases treated by this means (Cases 37, 53 and 93) were recent. The benefit of the treatment in these cases was most marked, and was in all probability quite as much due to the rest and internal medication as to the use of the tampons. This plan of treatment is certainly highly beneficial in recent cases, where there is subinvolution.

In a number of these there was so much sensitiveness of the pelvic tissues the pessary could not be tolerated. In other cases the presence of endometritis required topical applications, so that in these cases tampons were chosen instead of the pessary.

In Case 49 the senile vaginitis prohibited the use of the pessary, and in Case 23 the presence of adhesions prohibited the pessary. In this last case, gentle massage either stretched or loosened the adhesions.

The technic of the application of tampons is so well known it need not be described here further than to say that little benefit may be expected in their use unless the uterus is first replaced while the patient is in the knee-chest or in the exaggerated Sims position.

GROUP III.—TREATED BY PESSARY. RELIEVED.

CASE 16.—Miss A., aged 36. Retroversion. No complications. Backache. Profuse menstruation. Pessary gave great relief. Passed from sight after a few months.

CASE 21.—Mrs. B., aged 24. No children. Retroversion. Stenosis of internal os. Vicarious hemorrhage. Declined dilatation and Alexander's operation. Pessary gave marked relief. Passed from view in a month.

CASE 24.—Mrs. C., aged 40. No children. Retroversion only. Pessary. Marked relief.

CASE 32.—Mrs. D., aged 30. Retroversion only. One miscarriage. Pessary. Marked relief. Became pregnant.

CASE 42.—Mrs. E., aged 51. Four children. Retroversion, bilateral laceration of the cervix slight, dyspepsia, cystitis, internal medication, topical applications, tampons, then pessary. Marked improvement.

CASE 43.—Mrs. F., aged 34. Widow, no children. Retroversion, endometritis. Topical applications, internal medication, tampons, the pessary. Marked improvement.

CASE 45.—Miss G., aged 25. Retroversion and prolapsus of right ovary. Pessary and posture. Marked improvement. Not cured.

CASE 48.—Mrs. H., aged 33. Two children. Retroversion, endometritis, prolapsus second degree, chronic inflammation of ovaries. Curettement, rest in bed, general massage, tampons, then pessary. Should have been operated on. Much improved.

CASE 58.—Mrs. L., aged 32. Two children. Retroversion, prolapsus of uterus and right ovary. Slight laceration of the cervix and perineum. Rejected operation. Results unknown except that the pessary gave comfort.

CASE 69.—Miss J., aged 20. Retroversion, erosion, pelvic congestion. A few topical applications, internal medication. Pessary. Marked improvement.

CASE 70.—Miss K., aged 30. Retroversion, endometritis, ovarian hyperemia. Pessary and internal medication. Improved while at rest. Should have been curetted and had Alexander's operation.

CASE 77.—Mrs. L., aged 29. Retroversion, prolapsus of right ovary, not much pain, some bearing down. Pessary. Marked relief.

These twelve cases were treated by internal medicines, topical treatments and with pessary. These patients were all markedly benefited, and none of them have returned for operation. It is not to be denied that many such cases have relapses after a time and must patiently endure another course of treatment. In three of these cases there was prolapsus of one ovary. The ovary could be replaced, and the pessary made no pressure on it. In several cases it was found at first that the pessary could not be borne, but after using the tampons for a time the pessary was worn with comfort. It will be noted that four of these cases were unmarried women. Former experience has taught me that young unmarried women do not well bear the tampon treatment. I am convinced that such cases are best treated by the pessary or operative measures.

GROUP IV.—NOT BENEFITED BY TAMPONS AND PESSARY TREATMENT. COMPLICATIONS PRESENT IN EACH CASE.

CASE 50.—Miss A., aged 24. Retroversion, prolapsus of uterus, both ovaries, endometritis. Knee-chest position, applications to endometrium, tampons. Not benefited.

CASE 57.—Miss B., aged 24. Retroversion, retroflexion, left ovary prolapsed. Supposed to have gallstones. Tampons, pessary and posture used faithfully. No benefit.

CASE 82.—Mrs. C., aged 40. One child. Retroversion, prolapsus, some adhesions. Massage, posture and tampons. Patient refused operation. No benefit from treatment.

CASE 95.—Mrs. D., aged 33. One child, two miscarriages. Retroversion, laceration of the cervix, slight prolapsus, endometritis and both ovaries prolapsed. An invalid. Rejected an operation. Internal medicines, applications to endometrium. Tampons. No benefit.

CASE 102.—Mrs. E., aged 42. Two children. Retroversion, enteroptosis, movable right kidney, hyperplasia of the uterus. Exercise and tampon. Not much of any benefit.

CASE 104.—Mrs. F., aged 40. Two children. Retroversion, prolapsus of right ovary, laceration of cervix uteri, hyperplasia. Refused operation. Pessary a failure. Not benefited by tampons and exercise.

CASE 108.—Mrs. G., aged 33. One child. Retroversion, prolapsus, diastasis of recti muscles, prolapsus of right ovary. Internal medication, exercise and tampon treatment. No benefit.

These seven cases were not benefited. They declined operative interference. I predicted in most of them a failure, but promised to do the best for the patients aside from operation.

SUMMARY—THIRTY-FIVE CASES.

Thus we have cured by tampons or pessary	8 cases.
Relieved by tampons, etc.	8 cases.
Benefited by pessary	12 cases.
No relief	7 cases.

There were also many cases in which operation was advised and refused, so the tampon or pessary treatment was advised. They passed from view after first examination, so that it is impossible for me to state the results of the treatment.

It will be seen by this (Group 4) table that five cases were treated by exercise, tampons, etc., one by pessary alone and one by both pessary and tampons. Of the five cases treated by tampons alone there were two cases in which there was general enteroptosis, three of prolapsus of the ovaries and one in which there were adhesions.

One will ask why this form of treatment when the cases seemed so hopeless at the onset. We yielded to the importunities of the patients to do what we could for them aside from operative intervention. Doubtless the majority will in the end be operated on.

GROUP V.—TREATED BY MAJOR OPERATIVE MEASURES. CURED OR BENEFITED.

CASE 3.—Miss A., aged 25. Retroversion, slight endometritis, movable kidney. Ventrosuspension. Nephrorrhaphy. Cured.

CASE 6.—Mrs. B., aged 21. One child. Retroversion, prolapsus of ovary, endometritis, chronic ovaritis. Pessary failed. salpingo-oöphorectomy, ventrosuspension. Cured.

CASE 9.—Mrs. C., aged 25. One child. Retroversion, endometritis, slight bilateral laceration of cervix, prolapsed and enlarged left ovary. Curettage, ventrosuspension, removal of left ovary, resection of right ovary. Cured for a year, then right ovary became painful, enlarged and tender. Asks its removal.

CASE 17.—Miss D., aged 30. Retroversion, endometritis, prolapsus of ovaries. Curettage, salpingo-oöphorectomy, ventrosuspension. Cured.

CASE 29.—Mrs. E., aged 30. One child. Retroversion, prolapsed cystic and adherent ovaries. Salpingo-oöphorectomy, ventrosuspension. Cured.

CASE 31.—Miss F., aged 22. Retroversion, prolapsus of left tube and ovary, adherent right ovary. Salpingo-oöphorectomy, ventrosuspension. Cured.

CASE 40.—Mrs. G., aged 55. Seven children. Retroversion, prolapsus, rectocele and cystocele, senile endometritis. Curettage, anterior and posterior colporrhaphy, ventrofixation. Cured.

CASE 64.—Mrs. H., aged 28. One child. Retroversion, cystitis, prolapsus of one ovary, ovary cystic, perineal fistula. Operated for fistula, did salpingo-oöphorectomy and ventrofixation. Cured except the cystitis.

CASE 68.—Miss I., aged 34. Retroversion, prolapsus of right ovary, endometritis, gastro-intestinal disorder. Curettage, removal of right, resection of left, ovary. Ventrosuspension. Cured of pain and menstrual disorders. Dyspepsia much benefited. Cured.

CASE 75.—Mrs. J., aged 34. Four children. Retroversion, prolapsed and inflamed ovary, endometritis, patient an invalid. Curettage, extirpation of ovary and ventrosuspension. Patient regained her health.

CASE 97.—Mrs. K., aged 41. No children. Retroversion, prolapsus, cystic ovaries, endometritis. Treated with tampons and pessary. No relief. Curettage, salpingo-oöphorectomy, round ligaments, shortened by Tait's method. Health much improved.

CASE 105.—Mrs. L., aged 40. Two children. Retroversion, prolapsed and cystic ovary, hyperplasia of the uterus, ventrosuspension. Marked benefit.

CASE 112.—Miss M., aged 28. Retroversion, elongation of cervix, hypertrophied corpus uteri, endometritis. Curettage, Alexander's operation, later amputation cervix. Benefited.

Nine cured and four markedly benefited. Thirteen cases operated on in which benefit was experienced. In twelve cases an abdominal section was done and one or both ovaries were removed. In all of these cases the ovary removed had been inflamed for a considerable time and was thought to be incurably diseased, and hence was removed. A few of the cases had been previously treated by tampons and pessaries without benefit, but either cured or greatly relieved by curettage, suspension of the uterus and removal of one or both ovaries.

My experience with these and other cases leads me to the conclusions that where there is marked chronic inflammation of the ovaries as evidenced by severe, persistent pain in the ovarian region, painful defecation and many reflex symptoms, little short of resection or extirpation of the ovary will be of service in restoring the patient to health.

A word should be said regarding resection. In a previous paper,[1] based on a study of more than one hundred cases, the author shows that in his hands resection of the ovary is beneficial where the evidence of disease is limited to a single large retention and a few small retention cysts superficially situated, or in case of a single hematoma in which only part of the ovary was involved, and that even in such selected cases, fully 20 per cent. of cases were failures demanding a subsequent extirpation of the ovary.

This group shows the severe cases, those having so many and serious complications that any other treatment than operative was considered ineffective.

The method of ventrosuspension employed by the writer should be described. He did not follow the technic of Kelly. That method was abandoned by him some years ago because of the unfortunate reports of cases of difficult labor and of obstruction of the bowels. So far the writer has been quite well satisfied with the results in cases in which the following technic has been employed, viz.: The stitches were passed through the anterior surface of the body of the uterus just below the superior border. Two catgut stitches were carried one-fourth to one-third of an inch in depth into the

1. Amer. Gyn., December, 1902.

muscular coat of the uterus, the point of insertion into and exit from the uterus being about one-half inch apart and the stitches being separated by one-fourth of an inch. The ends of these threads were then carried through the peritoneum, deep fascia, muscular tissue and superficial fascia on either side. A third stitch, this one of silkworm gut, is placed in the tissues of the uterus more superficially and between the deeper catgut stitches. This stitch also passes through all the tissues of the abdominal wall on either side of the incision so that when tied it serves as a through-and-through stitch. The peritoneal surface of the uterus immediately over the three stitches imbedded in the uterine wall is scarified. The catgut stitches are tied first and then the silkworm-gut stitch.

From my description this would appear to be a ventrofixation, but it is not; it is a ventrosuspension. I have done a secondary operation for the removal of an inflamed ovary in two cases, and in both cases have found a single band of adhesion, in one instance one-third inch long and in the other one-half inch long, suspending the uterus as by a ligament from the anterior abdominal wall. The single superficial silkworm-gut stitch is important in preventing the formation of two bands. It is allowed to remain two weeks before removal. Several of my patients on whom this suspension has been done have become pregnant and passed through the period of gestation and labor without untoward symptoms. I do not put this forward as the only reliable means of suspension. It is, however, an efficient one and the one I prefer if neither or but one ovary is removed.

GROUP VI.—OPERATED ON WITHOUT MUCH, OR ANY, BENEFIT.

CASE 33.—Miss A., aged 18. Retroversion, marked endometritis, erosion, membranous dysmenorrhea. Curettage and Alexander's operation. Displacement rectified, membranous dysmenorrhea continues. Endometritis seemingly well for a time, then reappeared.

CASE 47.—Mrs. B. Widow. Two children. Retroversion, laceration of the cervix uteri and inflammation of left ovary. Curettage, trachelorrhaphy, extirpation of one ovary and resection of the other, ventrosuspension. Only partially relieved. After a time the remaining ovary became painful and enlarged. Patient begged to have it removed.

CASE 57.—Miss C., aged 24. Retroversion and retroflexion, left ovary prolapsed and enlarged, weak and nervous patient. Internal medicines, tampons and pessary did no good. Curettement, removal of one ovary, ventrosuspension. No relief, still an invalid.

In all three of these cases it would have been better treatment to have removed both ovaries. It was not done in the first case because the patient was a young woman, eighteen years of age. It was a very severe case of membranous dysmenorrhea, and was not at all benefited by the operation. In the second case, the woman was a widow, twenty-nine years of age, and wanted to marry again and bear children.

In our list there were two cases in which there were ovarian tumors producing the displacement. In both the retroversion disappeared after removal of the tumors. There were also three cases of small fibroid tumors of the uterus. Hysterectomy was done in these cases.

CONCLUSIONS.

My conclusions are:

1. Simple uncomplicated retroversion of the uterus gives rise to but few symptoms, the chief of which are backache and bearing-down pain. Painful menstruation occurred in 37 per cent. of the cases. Uncomplicated cases constitute but 7.01 per cent. (8 in 112) of the cases we have studied. Five uncomplicated cases were treated by the non-operative plan, three were cured and two greatly relieved.

2. The severity of the symptoms and the prospect of cure depends largely on the number and character of the complications. Prolapsed and chronically inflamed ovaries, endometritis and laceration of the cervix uteri constitute the most common and serious complications.

3. The most common complications are: Prolapsus of one or both ovaries, 42 per cent.; endometritis, 28 per cent.; laceration of the cervix, 24 per cent.; prolapsus of the uterus, 15 per cent.; adhesions, 13 per cent.; laceration of the perineum, 7 per cent.; movable kidney, 7 per cent.; ovaritis without displacement, 8 per cent. of cases. The most common and almost universal symptom is pain, 74 per cent. This includes painful menstruation, 36 per cent.; backache, 35 per cent.; pain in inguinal regions extending down the limbs. In but 21 per cent. of cases did habitual constipation exist. Various degrees of invalidism existed in all complicated cases.

4. In the treatment of the simpler and less complicated cases the non-operative treatment yields satisfactory results. Recent cases, especially those following labor, improve rapidly under this form of treatment.

5. Displacements of long duration, accompanied by the more serious complications, are not cured by this method, and the benefits resulting are scarcely sufficient to justify the effort.

6. Operative methods in the severest forms of displacement and complication are attended by a large per cent. of cures, and should be employed in preference to all other means. So large a percentage of these cases have multiple complications that two or more operations may be required in each case.

7. The danger attending the operative method of treatment is very small. In the twenty-one cases reported there was no mortality.

RETRODISPLACEMENTS OF THE UTERUS.

A FURTHER REPORT ON OPERATIONS ON THE UTERO-SACRAL AND ROUND LIGAMENTS.*

J. WESLEY BOVÉE, M.D.
WASHINGTON, D. C.

At the meeting of the American Gynecological Society in 1902,[1] and the following month before this Section,[2] I presented this subject, reporting 8 cases operated on by the vaginal and 3 by the abdominal route. At this time I desire to report 17 cases operated on by each of the two routes, together with some points noted from this experience. There has been no fatality or even notable morbidity in the 41 cases. In every instance of shortening the round ligaments the plan suggested by Webster and Baldy has been practiced. Curettage was done in every one of the 17 vaginal operations. In 3 of them trachelorrhaphy was done in addition, and in 8 perineorrhaphy and trachelorrhaphy. In one of these anterior and posterior colporrhaphy was added; in another posterior colporrhaphy up to the vaginal roof was done. In one the anterior vaginal wall was lengthened and attached at a higher plane to the cervix. In another case hemorrhoids were removed at the same sitting. In one an ovary was resected and in 2 others the peritoneal

2. Bovée: THE JOURNAL A. M. A., 1902, xxxix, 12-15.

cavity was entered through the cul-de-sac of Douglas for purposes of exploration. In 9 cases the round ligaments and in 8 the uterosacral ligaments were shortened. In none of these vaginal operations was both sets of ligaments shortened.

In the 17 cases by the abdominal route the round ligaments alone were shortened in 4 cases, the uterosacral ligaments alone in 7, and in 6 both these sets of ligaments were shortened. The vermiform appendix either normal or pathologic was removed 7 times, pelvic adhesions severed 7 times, ovaries resected 3 times and 1 appendage removed in 4 and both in 2 cases. In two instances the anterior vaginal wall was lengthened and in one of them it was detached from the cervix and reattached at a higher plane. In one case the ovarian ligaments were attached to the broad ligaments just posterior to the fallopian tubes by two stitches of fine catgut passed through them near the ovaries.

In 10 cases curettage was done. In one of these trachelorrhaphy and in another perineorrhaphy was added; in another perineorrhaphy and posterior colporrhaphy, and in 5 both trachelorrhaphy and perineorrhaphy were done. In one of these 5 posterior colporrhaphy was added. Thus it will be observed that in none was the reparative work limited to the round and uterosacral ligaments.

In my paper of last year an effort was made to show the very important part played by the uterosacral ligaments and the anterior vaginal wall, or uterovesical ligaments, in maintaining the position of the uterus. Reference was also made to the function of the round ligaments. I have found nothing to modify my views in that respect. I have done no other operation for retrodisplacement of the uterus in more than one year. Ventrosuspension, ventrofixation and Alexander's operation, all of which I formerly practiced without accident, I have abandoned. In my own work I have had but one failure in Alexander's operation, and that was probably due to faulty ligamentation about the cervix, allowing it to move forward too far, and a tendency to retention of urine. In a case of ventrosuspension the same faulty ligamentation led to recurrence of the retroversion and in one of ventrofixation. Edebohls[3] later found the cervix protruding from the vulva and the body firmly fixed to the abdominal wall.

The reasons for abandoning Alexander's operation were the journal reports of large numbers of cases of hernia, suppuration and relapses following that operation and the belief that the plans herein suggested are better. Goldspohn's modification of it was a great improvement, but not sufficient for all cases, as it was practically addressed to no supporting structures of the uterus other than the round ligaments.

Attaching the uterus to the abdominal wall never appealed to me as an ideal procedure, and yet, as a rule, it has maintained a popular position in the list of operations for retrodisplacements of the uterus. If the lower supporting structures of the uterus be faulty from maldevelopment or injury, one must expect failure, as a rule, to follow it. Such a structure[4] as this ligament traversing the peritoneal cavity would seem to be dangerous. If we are to consider the fatal complications that have been recorded we will at once see the force of this suggestion.

R. B. Hall[5] said: "I have had 3 cases of intestinal obstruction containing a coil of ileum around this little ligament left afterward. Two of the cases I have operated on, the other having declined operative measures. The case in which operation was refused died. Autopsy revealed a simple case of intestinal obstruction which could have been relieved by operation and life undoubtedly saved." Williams,[6] Jacobs[7] and Olshausen[8] report 3 cases of fatal intestinal obstruction from this false ligament, and Thomas[9] and Lindtors[10] report successful operations for the same conditions. We have further to consider the many cases of cesarian section positively due to interference with uterine development from these abdominal attachments. Only two weeks ago I saw an example of it. In this case the operation had been done by an expert, but the evidence of its causal relation to impossibility of delivery *per vias naturales* was positive.

The results in these 41 cases are nearly perfect and have determined me to examine very critically every patient in whom surgical treatment of retrodisplacement is contemplated to decide the exact causes of the displacement and to plan the measures to be employed. While a lacerated perineum is not *per se* productive of posterior uterine displacements, yet straining at stool incident to its resulting constipation may produce them. Laceration of the cervix, if deep, very markedly tends to uterine retrodisplacements. Lacerated vaginal walls—particularly its roof—is a strong etiologic factor. All these conditions should be recognized and given their proper positions in etiology that treatment may be scientifically applied. In many cases, particularly in women who have had tedious labor or have been delivered carelessly with forceps, the fascia by the sides of the rectum and which goes toward making up the uterosacral ligaments, will be torn and much relaxed. In such the vaginal route is not indicated. Here abdominal section and the Trendelenburg position are imperative. Intraperitoneal conditions are best mastered by it, and one knows those conditions, which is not the case with the vaginal route. I have not the intrepidity that necessarily accompanies severing intraperitoneal adhesions without the sense of sight. I know it is done, but the inability of the skillful diagnostician to always detect abnormal pelvic conditions leads me to fear this procedure. Therefore, I prefer always to open the abdomen when such work is to be done.

DISCUSSION

ON PAPERS OF DRS. DUNNING AND BOVÉE.

Dr. G. Betton Massey, Philadelphia—I have never failed to get perfect results in these cases of retroversion and retroflexion without ovarian or tubal disease. All the symptoms disappear, although I believe that in actual retroflexion I have never straightened the uterus. It is my belief that the posterior wall of the uterus is sclerosed and atrophied and that nothing will remedy this, though perfect health may be restored. These patients are entitled to the best help, and none of the uncertain operations are necessary. For cases complicated by ovarian disease I presented a method last year at Saratoga which has evoked considerable interest since, and I am sure that it will be very valuable. It is the cataphoresic diffusion of mercury through the abdominal wall into the chronically inflamed parts, thus sterilizing the disease. I have since verified the peculiar experience then related, in which menstruation was suppressed for a month or so after treatment. Such treatment may have to be greatly prolonged, but many patients are also cured of the patulous pus tube

and the adhesions that follow a pelvic inflammation. I think that if Dr. Dunning would substitute this treatment for the method which failed, he would have a higher percentage of successes.

Dr. E. S. Lewis, New Orleans—It is essential to remove the adhesions which are responsible for the displacement by massage, trachelorrhaphy or operations on the vagina or perineum; then, even if the retroversion continues, in many instances the symptoms are relieved. My usual treatment in suitable cases is the use of the pessary; cases in which all inflammatory complications have been subdued entirely. I have derived marked benefit from the pessary and still resort to it, although not as frequently as in former times, as it is an instrument which has and may do a great deal of harm. Of the operative methods I prefer ventrosuspension, not ventrofixation.

Dr. Walter B. Dorsett, St. Louis—I have not abandoned the pessary, and do not expect to. The pessary has a place to-day as it always had. Some inflammatory cases with adhesions can be treated for a considerable length of time with a lamb's wool tampon, and finally the pessary can be worn to good advantage. A great deal of harm has been brought about by Kelly's operation. I do not believe in tipping the uterus upside down and fastening the posterior wall of the uterus to the anterior wall of the abdomen. It is not in accordance with physiology. On account of the leverage it is made to draw out pieces of peritoneum to form long bands. These bands may catch intestinal loops and serious trouble result. But if the anterior part of the body between and below the two attachments of the round ligaments is attached to the anterior abdominal wall I can not see that any harm can come from it. I have had five cases of labor following ventral suspension, and one of the cases has been delivered twice. I do not see how we can have any entanglement of the bowel if the cases are selected properly and the anterior wall of the uterus brought in close apposition to the uterus. There is no leverage on which the uterus can pull back, but it is held firmly against the abdominal wall without any possibility of the intestines dropping in front of it. If turned back the other way we have the entire intra-abdominal pressure bearing down on the uterus and pulling out these adhesions.

Dr. S. E. Milliken, Dallas, Texas—I believe that we all to some extent use the pessary, but it is a question whether a pessary can replace the uterus. The pessary is indicated in cases in which there are no inflammatory adhesions; in other words, in retrodisplacements of a more or less congenital or acquired type without any inflammatory condition.

Dr. C. O. Thienhaus, Milwaukee—The uterus belongs in the pelvis, and there is no logical reason why we should perform abdominal section and abdominal suspension when the same work can be done with more safety to the patient and better immediate and remote results by way of the vagina, and at the same time by vaginal suspension the uterus is left in the place where Nature placed it. All surgeons with a little experience in vaginal celiotomy concede that this operation has great advantages over abdominal section so far as the immediate and remote safety of the patient is concerned. Conceded this, the logical consequence is, that everything ought to be performed by this route, if possible. It is true that vaginal celiotomy and suspension are hardly applicable for the general practitioner, but the specialist ought always to bear in mind that the welfare of the patient is the first law which has to govern our methods of operation, not difficulties of operative procedures, which can be overcome by practice. Whether one prefers vaginal shortening of the round ligament following the methods of Vineberg, Wertheim or Ries, or vaginal suspension in cases of retroflexion of the uterus is merely a matter of personal like or dislike. But it must be conceded that vaginal shortening of the round ligament allows a greater mobility of the uterus. I prefer the following method of vaginal suspension: After an inverted T-shaped incision on the anterior vaginal wall, and thorough freeing of the bladder from the cervical part of the uterus the vesico-uterine fold is opened by a transverse incision, then the uterus is drawn forward by a tenaculum forceps and drawn into the vagina. If it is necessary to perform conservative or radical work on the appendages after this has been done under perfect guidance of the eye, the uterus is pushed back and now fixed by one silkworm-gut suture 1.5 to 2 centimeters above the internal os. This suture, passing through vagina, peritoneal fold and uterus, closes the abdominal cavity and remains for six weeks. What is accomplished by this? The vesico-uterine fold which formerly reached down to the point of the internal os now only reaches to the middle of the body of the uterus, but the fundus of the organ is left free and movable, so that no disturbance can occur during future pregnancies. In chronic inflammation of the appendages with adhesions in Douglas' pouch, parametritis posterior, etc., I usually employ hot douches, massage, etc. (not in pus cases), for two weeks before the operation. I do not by this time make the uterus movable, I open the posterior cul-de-sac first, and after freeing the uterus from the adhesions the anterior celiotomy is performed in a manner as cited above. In such cases a strict diagnosis and selection must be made before operation, as in some of them it is preferable to use the abdominal route because of too dense adhesions. Many women afflicted with retroflexion, who would not submit to abdominal suspension, have, after learning the advantages of the vaginal route, readily consented; it is my opinion that many women, if they knew the difference between abdominal and vaginal celiotomy, would still less allow abdominal operations. I never lost a case of this class operated on by the vaginal route, and I never saw an infection. The operation can be performed in uncomplicated cases in from 5 to 10 minutes, and the patient can leave the hospital on the eighth day, provided no plastic operation has been found necessary. I believe, furthermore, that this operation will do away with many a pessary and its inconveniences. After proposing this method to a patient wearing a pessary I have no difficulty in obtaining her consent for operation.

Dr. J. H. Carstens, Detroit—Dr. Thienhaus does a Mallincrodt operation and a Duehrssen, which is all very good, and yet once in a while there comes a case in which you can not use either. What is to be done? If a uterus that is turned back is turned over there results a general ptosis of the uterus and of the other pelvic organs; there is a dragging on the bladder, and all these organs can not be lifted up by that kind of an operation. In such cases a ventral suspension is required, or a sacral ligament operation, or a shortening of the round ligament. Dr. Dunning covered the whole ground; he simply said that a retroverted uterus was a complicated disease, some cases can be cured by the pessary and local treatment; some cases with an operation, and some can not be cured by either method. I do not see what we can accomplish in some of these cases by insisting on an operation. Some operations are very good in a certain number of cases, but are not worth a continental in others. It is a question of diagnosis, and then apply the treatment indicated in that particular case. Bovée's operation is a splendid one in certain cases, but he does not do that operation in every case. He selects his cases and always does the operation that is applicable in that particular case.

Dr. V. M. Showalter, Point Clear, Ala.—We have to face conditions and not theories. In addition to the ptosis of the pelvic organs, there is a certain amount of hyperplasia which, with the congestion of the organs, makes it necessary to attempt to restore the organs to their normal condition. Allow a certain period for the absorption of exudate which may have accumulated as a result of the passive congestion before any radical steps are taken for fixation of the uterus in the abdominal cavity. When this course is pursued the percentage of failures will be less after a properly selected pessary has been used; and I would like to lay special emphasis on the proper selection of a pessary according to the individual requirements of the case.

Dr. H. O. Marcy, Boston—Fifteen years ago we had reached a great point, we thought, when the Alexander operation gave us the shortening of the round ligaments. After a little while we found that the operation was a failure. It was not physio-

logically correct. But occasionally good results follow the Alexander operation. Opening the abdomen, however, is the most important procedure, because there is almost always some other condition than that described by the last speaker. The uterus in its normal position is freely movable. When it is out of place there is suffering and discomfort and a whole train of pathologic symptoms. Only by opening the abdomen can we determine what these other factors are. Then we are able to shorten the round ligament so as to restore the reproductive organs to their normal condition, and that is by ventral suspension according to physiologic principle. This is so easy and clear and successful in the hands of an aseptic operator that we have little to look for in the way of improvement. The operation is ideal. The shortening through the vagina is not as satisfactory in my hands as is the abdominal route, since by this method it is impossible to determine accurately the condition of the pelvic structures.

Dr. Edwin Ricketts, Cincinnati—I advocate the abdominal route. As Dr. Dunning has said, each case is a case in itself and each man must meet the emergency or let the cases alone. One thing not mentioned is pregnancy after ventrofixation. It has been my misfortune to look after some cases that have had all kinds of shortening of the round ligaments done. One case, a woman of 27, had her right ovary removed and had a ventral fixation. Four years afterward she became pregnant twice, and the general surgeon who saw her thought she should not go on to full term. Abortion was resorted to at two different times. Finally at the third pregnancy she consulted a gynecologist, who stitched the uterus to the abdominal wall and told her to let the pregnancy continue. She was delivered of a child at full term. The anterior wall of the uterus had been brought up tight against the peritoneum and the ligament that had formed was four inches in length by actual measurement. After ventral suspension a woman takes her life into her own hands, but the case should be explained fully to her, and if she ever becomes pregnant she ought to agree to surgical intervention. As to the pessary, I want to caution those who are so sure as to the healthy conditions in round ligaments and ovaries. If the abdomen is opened a diseased ovary is often found with the appendix attached to it. Pessaries have been on the down grade. If pessaries are to hold up the uterus, to allay the uterine congestion and overcome the dragging of the appendix, our friend Massey is correct when he says he will put his patients on their backs and produce contraction of the ligaments. It is a much better and safer operation than to resort to the pessary in cases in which you do not know what is inside.

Dr. F. F. Lawrence, Columbus, Ohio—There is difference of opinion because we approach cases with a clinical rather than with a philosophic eye. Any operation or method based on sound philosophy will and must prove correct; and any operation based on false philosophy will and must prove faulty. Is the replacing of one pathologic condition by another sound philosophy? Do we ever find as a physiologic condition a fixed uterus? Is there ever a physiologic exception, other than the broad ligament, to the rule that the ligaments are merely guy-ropes which keep the uterus from tilting in one direction or another? If that be true, then the one factor to ensure success in removing the conditions which cause the retroversion or flexion is to first restore the tension of the broad ligament, giving the uterus support from above as it should have, and restore the natural support from below, whatever it may be. Many cases, if caught when descending, can be cured by electrical treatment by restoring the tone of the tissues. Put them to bed and keep them quiet. Pelvic massage has its place as much as any operation and should be given in these cases. It is much better than an operation which is finer in theory than in result.

Dr. C. Lester Hall, Kansas City, Mo.—While physiologic processes are referred to, I am surprised that nothing has been said of Nature's way of correcting these displacements. If these patients who come to me for such conditions are married I tell them frankly to become mothers. They become pregnant with the uterus in a good physiologic condition. A week or ten days after the child is born they are put in the genupectoral position several times a day. The uterus is kept in position, the woman kept in bed for three or four weeks until the uterus has returned to its normal size and position, and they are cured women. I have done this repeatedly, and I believe the easiest way is the best, and that is the physiologic or Nature's way.

Dr. A. Palmer Dudley, New York City—In pregnancies after ventral suspensions I have measured the ligament immediately after delivery and a week and two weeks afterward. I have also opened the abdomen and taken exact measurements in cases where an appendicitis or disease of the appendages required a second operation. Of my 269 cases—and in each, bear in mind, treatment was given first—I find that I did 99 ventral suspensions without a death, and following that I am sure I can recall to mind more than eight deliveries that I made myself, and I had no difficulty in having my patients go to full term. I do not denude the fundus, but take the fundus half way between the tubal entrances and pass two silkworm-gut sutures into the uterus, without touching the mucous membrane, and out through the abdominal wall completely through the skin. Then I scarify the top of the uterus, just as in vaccinating, let it come up loosely against the peritoneum of the anterior abdominal wall, first loosening the peritoneum a little on either side with my finger. The uterus remains in that position with the stitches in place for three weeks. Then the sutures are withdrawn and the peritoneum drops down to form a ligament and there is no chance for an intestinal obstruction, but it is a new urachus running from the abdominal wall to the top of the uterus and off to the base of the bladder. The ligament is triangular in shape. Ventral fixation is a pernicious thing and should never be done, from the obstetric standpoint, bear in mind, that the uterus does not rise perpendicularly toward the diaphragm, but it comes forward; the abdominal muscles distend and the fundus of the uterus is not more than two inches above the fixation point when the woman is ready for delivery.

Dr. L. H. Dunning—We should more frequently consider the treatment of disease from all its bearings. We have considered the operative treatment too frequently to the exclusion of all other forms of treatment. I have seldom found any one in any of the meetings I have attended who would consider anything but operative treatment. I would not, in my own family, trust a man who had nothing in his head but operation. I like to operate when it is necessary, but I abhor an operation when it is not necessary. I have done all the various operations, as most of you have, a good many times. My work with ventral suspension has yielded the best results. I have been at a loss to understand how so many cases of obstruction of the bowels occur in the hands of others. I never had a case of obstruction, and I know of a dozen women who were confined without difficulty, although I know that obstruction will occur without any assignable cause. I know of one case of kinking of the bowel from adhesions of the intestine to the anterior wall of the abdomen. There was a little sepsis, the bowel stuck there and obstruction occurred. My method of ventral suspension agrees almost exactly with that of Dr. Dudley. I do not take my stitches out through the skin, however, although I put one silkworm-gut stitch between the other two and bring that one out on the skin. It accomplishes the same result. The middle stitch prevents the formation of two bands, which is important in these cases. I have never seen any unpleasant effects from this operation. There is free movement of the uterus with a band about one and a half to two and a half inches in length. Twice I have reopened the abdomen for other purposes and found a single band. I would put forward ventral suspension as one method for overcoming retroversion of the uterus when all other methods failed. I think Dr. Bovée will come back to ventral suspension after a while. I have been through the same experience from the beginning, only to drop one method after another. Dr. Ricketts condemned the pessary because he does not know what is inside. Does he open the abdomen of every case that comes to him? That is what we must conclude from

what he said. That is a perfect fallacy. What Dr. Hall said, according to my experience, is true. I wish to call your attention again to Dr. Munde's article,[1] in which he went all over this ground and showed that only 5 per cent. of cases were cured when they become chronic by tampons and pessaries, but that a large percentage of cases were cured after confinement by the posture method, by the exercise treatment and the use of tampons and pessaries in suitable cases.

Dr. Wesley Bovée—Some use sutures through the skin in ventral suspension. I never put a suture through the skin in any operation; I am opposed to it. We forget an element here, the uterosacral ligaments. They have a tendency to drag the cervix backward and upward. When abnormally attached they have a tendency to drag the fundus backward. Another element is whether this attachment is abnormally high, or whether the anterior vaginal wall is abnormally low when it draws the cervix forward. What is the use of ventral suspension in such a case? The uterus stands straight up; it is allowed to come forward against the abdominal wall; intraperitoneal pressure pushes it down. I mention one case in my paper where the ovaries had been removed and in which I did a ventral suspension. Dr. Edebohls removed the uterus afterward and found the cervix protruding from the vulva and the fundus still firmly fixed to the anterior abdominal wall. What is the use of a ventral suspension? Suppose after a tedious labor you have torn off these uterine supports and lost the supporting power. The only method of treating that case should be to correct the injury that is done. You must do that work before you will do successful work. If something else is needed do it. Treat everything that must be treated. I did not for one moment expect to be understood as saying that these operations were applicable to all cases. I treat many of these cases by the use of tonics, pessaries and massage. You can tell at the beginning whether you can do anything with such treatment. But you can not expect massage to do any good when the cervix is badly torn, or the perineum ruptured and these ligaments torn all to pieces. I put these women, not on their backs, but on their abdomens, so that the uterine fundi will drop forward. That is the same position I put them in after an operation on the uterosacral or round ligaments. I do not let the weight of the uterus drag on tissues I have sutured. I want the ligaments to be as lax as possible during healing. As to the postural treatment in cases following delivery, I agree in what has been said except that I would never feel it necessary to introduce my fingers into a woman's vagina within a week or ten days after delivery for purposes of reposition of the uterus; nor would I in the first week of labor put a woman in any position, such as the genupectoral, that taxes her already exhausted vitality. I would also fear the occurrence of embolism. These methods which I have suggested are in the line of physiologic repair, and are directly in opposition to the ventral suspension, which is unphysiologic.

EXERCISE AS A MODE OF TREATING DISEASES OF THE HEART.*

N. S. DAVIS, Jr., A.M., M.D.
Professor of Principles and Practice of Medicine and Clinical Medicine, Northwestern University.
CHICAGO.

Our knowledge of diseases of the heart is of comparatively recent date. It is true that Vesalius did much to make known the anatomy of the organ and that Harvey demonstrated its purpose or function. This much was learned in the sixteenth century, and during the following centuries contributions were made slowly to a knowledge of its pathology; but methods of physical diagnosis by which its pathologic states could be recognized during life were not discovered until the end of the eighteenth and first quarter of the nineteenth centuries.

The opinions of former generations of medical men have not yet been outgrown by laymen, and many of the latter think that a permanent anatomic defect in the heart means sudden death, death which is especially apt to be caused by physical exertion. The fact that overexertion, either mental or physical, can cause dilatation, and, perhaps, fatal weakness, of the heart when it is defective, led to the prevalent opinion just expressed. Stokes, in the middle of the nineteenth century, was one of the first to register his disbelief in the danger of all exercise, and even faith in the curative effect of suitable kinds, for he wrote: "The symptoms of debility of the heart are often removable by a regulated course of gymnastics or by pedestrian exercise, even in mountainous countries, such as Switzerland or the highlands of Scotland or Ireland." As late as 1876, however, Rosenstein wrote of exercise: "It must be taken cautiously, and all severe exertion, such as mountain climbing, etc., should be strictly avoided; but it is just as injurious to condemn a patient with heart disease to perfect quiet." Between 1862 and 1872 Sutorburg of Stockholm and Zander described their experience in the treatment of cases of heart disease by gymnastics. In 1884 Oertel announced the results of his trials of more vigorous exercise, such as mountain climbing, and elaborated the mode of treatment which bears his name. Later Schott of Nauheim made known his method of treating these cases by "resistance gymnastics" and the carbonated, saline baths, whose curative power in such diseases had been made known earlier by Beneke. During the last thirty years massage has also been used for the treatment of heart diseases.

From this brief and rather fragmentary history of exercise as applied to the treatment of heart disease, it is seen that four forms: 1, Massage; 2, Swedish gymnastics; 3, mountain climbing, and, 4, resistance gymnastics, have been used. As advocated for the treatment of heart diseases, each form of exercise has one important factor in common, which is that exercise must be increased in severity very gradually and breathlessness must be avoided.

Valvular lesions of the heart rarely are corrected by subsequent changes in the valves, but a strong heart commonly will compensate for the valvular defect. Therefore, the prime indication for treatment in valvular disease of the heart is to make, and to maintain, a strong heart muscle. This evidently is also true when we have to do with degenerations or fatty infiltration of the heart or dilatation from any cause. It is well known that voluntary muscles atrophy and degenerate when they are unused or used little, and that they can be made to grow strong only by gradually, day by day, increasing the amount of work which they do. These statements are as applicable to the heart as to voluntary muscles. Moreover, as the latter may be greatly injured, even strained beyond repair by an unusual, sudden and excessive exertion, so may be the heart, and it is much oftener.

These well-known facts afford a logical basis for the employment of exercise in treating heart disease. Drugs, such as digitalis, may temporarily contract the organ when it is dilated, and strengthen it when it is weak. But permanent recovery of strength is only obtained by improving the nutrition of the heart and by relieving

1. Amer. Jour. of Obstet., 1888.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

it of excess of work. Both of these objects can be accomplished by judicious exercise of the voluntary muscles.

When the heart is weak or compensation is broken it beats rapidly, feebly and often irregularly. Each muscle fiber does not do its whole duty, but contracts imperfectly; therefore, the heart does not completely unburden itself. This is partly due to the weakness of the heart, and often also to the accumulation of blood in the viscus and consequent distension of it.

The effect of muscular exercise on a weak or dilated heart has been carefully studied during the last few years. The most striking effect is that often obtained when the heart is dilated, namely, rapid and very noticeable contraction of it. When the heart is weak and beating rapidly, but is not dilated, the effect is less striking, only a slightly slower and stronger beating being produced. Not infrequently the apex beat of a dilated heart will move an inch nearer the sternum during "resistance gymnastics," or a weak heart will beat from 5 to 15 beats less per minute.

These results are undoubtedly effected by the extra amount of blood which is drawn into the muscles when they are used. Consequently the heart is depleted and arterial pressure is lowered, so that it works against less resistance.

Unquestionably, the first or immediate effect of muscular work is to increase blood pressure, but this rise is temporary and is followed by a more persistent fall, which is caused by the dilatation of arterioles in the hard-used muscles, a dilatation necessitated by their demand for food and for more rapid removal of waste by irrigation. The primary increase of pressure is in proportion to the degree of exertion, but the secondary fall is more dependent on the duration of muscular movements, and the number and size of muscles used. It is, therefore, possible by trivial exertion to avoid an increase of pressure, and by using many of the large muscles to ultimately lower pressure very greatly. This is the reason for what may be called the first rule in applying exercise to the relief or cure of heart diseases—that is, *the muscular effort must be slight, but numerous large muscles must be used.*

Mitchell, Brunton and others have shown that massage produces an increased flow of blood through the voluntary muscles, and the effect of athletics on blood pressure has been studied by Ray, Allbutt, Oliver, Moso and others with, among other conclusions, the discovery that the average blood pressure of athletes is habitually lower than of those who lead a sedentary life.

The walls of blood vessels deteriorated by advancing years, syphilis, alcohol or lead, respond less readily when the muscles which they supply demand more blood than they should. But as atheromatous and degenerative changes are often chiefly confined to visceral arteries, massage and resistance exercises prove very helpful in certain cases, and disappointing in those in which the arteries generally are involved.

Although the aorta and left ventricle can be unburdened by exercise, it might be supposed that the veins and the right side of the heart would soon be overdistended. This will take place if movements are made with rapidity and the exertion is considerable, but when the movements are made slowly and the exertion is slight it does not happen. Much of the serum which flows into the moving muscles is diverted into the lymphatics, and the movement of lymph is, therefore, greatly accelerated. The more rapid bathing of the muscle fibers with fresh lymph improves their nutrition, and the more rapid flow of lymph hastens the removal of waste products. Just as in these ways the voluntary muscles are made stronger, so the heart is, because when unburdened it contracts more forcefully, which insures a more generous supply of blood through its own arteries and lymphatics.

Undoubtedly, deep respiratory movements which exercise insures play an important part in improving nutrition, for not only is the blood more thoroughly oxygenated by them, but the fully distended lungs hold more of it, and, therefore, unload the right ventricle. The variations in intrathoracic pressure, produced by deep inhalations and complete exhalations, help greatly the onward flow of venous blood and lymph. They may also aid materially the filling and emptying of the cavities of the heart. Therefore, the second rule for the conduct of exercise for the relief of cardiac disease is naturally that *respiration must be deepened, but not hurried,* for quick, irregular and imperfect respiratory movements will lessen the variations in intrathoracic pressure, impede venous and lymphatic circulations.

The third rule is that *the exercise must be graduated.* At first only the lightest should be used, and very gradually it must be increased in vigor, and it must be adapted to each case. Under no circumstances must breathing or the heart be hurried.

Massage and resistance gymnastics are the gentlest forms of exercise, and should be first used in all cases. The latter require less training than do the former, and can be best directed by a physician. They therefore seem to me most generally useful. They consist in slow flexion and extension of the hands, then of the forearm and later of the whole arm. Similar movements of the feet and legs, of the head and of the body at the hips should follow those of the hands and arms. The arms, legs and body also may be slowly rotated, and the latter may be bent to the right and left, as well as forward and backward. These movements should be repeated for from eight to fifteen minutes. At first no resistance need be made, but after the two or three first seances a trifling resistance to each movement can be interposed by the nurse or physician. This resistance can be gradually increased day by day, but never should be enough to increase the rapidity of the heart or respiration. When a moderate degree of resistance is well tolerated, patients can be taught to resist movements of flexion by the extensor muscles or of extension by the flexors.

Hill climbing is not adapted to cases of very considerable weakness and dilation, such as can be treated by massage and resistance gymnastics. It is, however, a mode of exercise which is particularly adapted to those who have first been trained by the other method, or who are fairly strong at the start. Deep breathing is sure to be caused by hill climbing, and undoubtedly is a most important factor in bringing about improvement. Moreover, a more rapid loss of fluid by evaporation from both lungs and skin is certain to take place. However, the distance walked, the grade climbed, the frequency of the stops for rest, must be carefully adapted to each person. So soon as the heart is felt to thump or the breathing to shorten, a stop should be made, and deep breaths and a rest taken.

Only those who have had personal experience in training people, either with or without heart weakness, can appreciate fully the effect of graduated exercise.

Although resistance gymnastics are only one element of the Schott treatment, the carbonated saline bath being the other, by abundant experience I have learned that the exercise alone will accomplish the desired purpose,

although undoubtedly the baths are useful. So, too, hill climbing is only one element of the Oertel treatment, a restriction of food and drink being the other; both of these last are only applicable to those patients who are obese, or at least are well filled out with fat.

All forms of heart disease, accompanied by muscular weakness, with or without dilatation, can be treated with hopefulness by exercise. The best results are obtained in cases of dilatation which are due to high arterial pressure or physical exertion, and in which there is no, or trifling, degeneration. In the early stage of muscular degeneration recovery can be effected. If, however, there is much degeneration or a cause for its increase, only temporary improvement will be obtained.

For the treatment of obesity and fatty infiltration of the heart, Oertel's treatment is particularly well adapted, although other kinds of graduated gymnastics, with a suitable regulation of diet, will also give good results.

Resistance gymnastics and massage are adapted, I believe, to a group of cases for which I have not seen them advised. I refer to convalescents from acute endocarditis, whether from rheumatism or other infection. All practitioners have observed frequently a break in compensation soon after patients begin to move about. This is because the heart has not had the time or the training necessary to enable it to compensate for the valvular defect, and a small amount of exertion strains and dilates it. Such patients should be kept in bed for at least two weeks after the acute infection which causes the endocarditis is over. During the last half of this time, resistance exercise or the gentlest massage will greatly help promptly to effect compensation. This treatment should, if possible, be continued for some weeks longer, and the amount of walking, stair climbing, etc., should be carefully regulated.

Of chronic valvular diseases the mitral oftenest respond to gymnastics, but numerous cases will be met in which compensation can not be restored by any treatment. Aortic valvular affections are less certain to be improved, for breaks in compensation occur in them frequently after very considerable hypertrophy has taken place, and when a little more can not afford relief.

Although when the heart degenerates or grows weak because of atheromatous arteries a perfect recovery is rarely effected, a temporary improvement often is. Even angina pectoris is not a contraindication. I have seen several cases of the latter disease very greatly improved by resistance gymnastics.

I do not wish, while advocating exercise for the treatment of heart disease, to leave the impression that drugs are not sometimes needed, or that it will certainly effect recovery. But it is a mode of treatment that should not be neglected and one that is essential in many instances.

DISCUSSION.

Dr. W. W. Tompkins, Charleston, W. Va.—I agree substantially with all Dr. Davis has said. I believe we are sometimes a little derelict in our duty in not exercising sufficient care to prevent the patient from taking too much exercise. I will mention two cases which I lost. One patient was 48 years of age with a well-marked organic heart lesion, and I advised against exercise and had him change his office and sleeping quarters from the upstairs to the ground floor. This patient got along very well, and I had cautioned him never to take any severe physical exercise. One day his son called him to assist in turning a skiff, and while doing so he dropped dead. In the other case I had advised against exercise, but one day he asked permission to play baseball. I advised against it, but he played anyway; as he ran around the bases he dropped dead on the third base. Statistics given us by Oertel of Germany and Zivink of Australia certainly show that under certain circumstances great benefit is derived from moderate exercise. In addition to the medical treatment it is probable that most of these cases should take some form of iron. How often do we find cases of heart diseases suffering from anemia? I believe in the majority of instances a certain amount of exercise is advisable, but in some instances I believe that exercise should be only passive, such as riding about in sunlight and air, and when we give this advice we should add a caution against overexertion.

Dr. Solomon Solis-Cohen, Philadelphia—We agree that the indications are largely governed by the condition of function. The endeavor must be to equalize function—to restore the balance of function. When there is depression of a function it may be exalted or other functions may be depressed to its level as seems most wise in the individual case; and similarly overexalted functions may be depressed or normal functions temporarily exalted. In cardiac disease, as a rule, we are compelled to pay more attention to the depression of normal function to the level of the impaired heart than to exaltation of cardiac function, hence we caution against overexertion. In the discussion on diabetes it was thought that physicians had gone too far in restricting the carbohydrate diet and perhaps we have also gone too far in restricting exercise in cases of heart lesions. Of the value of depressing the general function to the level of the impaired function there can be no doubt, but at the same time the endeavor should be made to bring up impaired function to the highest level consistent with maintenance of life.

Dr. N. S. Davis, Jr.—There is no doubt that overexertion, or exertion made suddenly and considerable in amount, will often cause a fatal result in heart disease; and in those without heart disease this may cause a temporary condition which will produce illness for the time being. On the other hand, take the cases of heart lesion referred to by Dr. Tompkins; if those individuals had been taught by suitable exercise to understand just how much they could do and how much they could not do, the one would not have played baseball and the other would not have attempted to lift the skiff. Furthermore, if the heart had been properly exercised the probabilities are it would have been able to withstand a certain amount of extra exertion—I do not mean the amount put on it in these two cases. There is no doubt that a weakened organ must be carefully watched, but it can often be made stronger by suitably arranged exercises. Moreover, by these exercises the patient will learn to know just about how much exercise he can take and how to regulate that exercise. This is a very important result of such treatment.

THE FUTURE OF PREVENTIVE MEDICINE.*

H. A. MOODY, M.D.
Professor of Materia Medica and Therapeutics, Medical College of Alabama.
MOBILE, ALA.

Among the many subjects claiming the attention of this Association, none can be more important to the welfare of humanity than that of preventive medicine. The term implies an organized effort by the medical profession to protect mankind from attacks of those recognized causes of disease and death that can be avoided or destroyed. To avoid or destroy the cause is not only to escape the disease, but also to prevent the generation of countless germs fraught with danger. The list of pathogenic organisms whose appearance, characteristics and behavior are sufficiently known to enable us to avoid or destroy them, contains the names of the germs whose invasion of the human system re-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. S. Fulton, Seneca Egbert and H. M. Bracken.

sults in the diseases most widespread and fatal, the scourges to which five deaths out of every ten may be traced.

Think of the results in one decade were the death rate diminished by 50 per cent.; of the families now bereaved that would remain unbroken; of the busy brains and hands now stilled that would be adding their quota to the wealth and comfort of the world. Yet that such a beneficent result is within the reach of organized effort a consideration of the facts below enumerated will demonstrate. Think of pulmonary tuberculosis: About two people out of every hundred are infected with tuberculosis. Out of every seven deaths, one is from consumption. Over one hundred and fifty thousand people die of it every year in the United States. The cause of this "Great White Plague" is well known. Its presence in a sufferer's tissues is readily recognized, and the precautions, which would prevent the escape of a single germ from this source of contagion are few, simple and easily adopted. Yet all over our country the sun shines daily on thousands of perambulating incubators of death, each one of whom, during the hours of daylight, distributes around him germs enough to infect every man, woman and child in the republic. All this can be remedied only by preventive medicine. Think of typhoid fever, of which it might be said that every case is the result of criminal ignorance, or still more criminal carelessness. Think of smallpox, and Jenner, but do not consider that victory complete while thousands yet deny the efficacy of vaccination, or while men like Lord Kelvin, purest gems of intellect, but with one faulty facet, deny its usefulness and support their position with arguments too puerile to be worthy of respect. Think of pneumonia, with a death roll next to that of consumption, with a known pathogenic bacterium, but without, as yet, any general effort to limit the germs to the person of the patient. And remember the most widely distributed of all diseases, malaria, with its recently discovered possibilities of prophylaxis; the equally marvelous facility with which yellow fever can be corralled and its ravages stayed; and the almost incredible triumph of sanitation over bubonic plague in its subterranean stronghold under San Francisco.

Though much has been accomplished, it is only the beginning. It merely points the way to the final goal, which should be nothing less than the absolute eradication of recognizable infectious germs. The causes of most of the diseases above mentioned, and of many others unenumerated, can be, and should be, swept from the face of the earth. Hydrophobia is almost unknown in North Germany. The reason is obvious. All dogs are muzzled; if one runs mad the poison dies with him. For yellow fever and malarial diseases the mosquito bar is analogous to the muzzle for hydrophobia. Infection can be prevented from escaping. Against every germ there can be found a means of protection.

The means necessary to accomplish the desired end are already recognized in many instances. It is a most important element of any enterprise to know what is needed. The writer believes that, in this instance, what is needed is dissemination of knowledge that will enable the people, lay and professional, to understand and apply the principles of sanitation, antisepsis and asepsis, in order to avoid or destroy the germs of disease. No organization, however worthy or sincere, can hope to accomplish any general or national object unless supported by an enlightened public opinion. In this matter, a mere national coöperation would not suffice. To rid the world of consumption and typhoid requires international coöperation, only to be hoped for when founded on international enlightenment. To eradicate the germs of those diseases from our country alone would necessitate a perpetual and almost impossible quarantine against reinfection. Much easier than this would it be to render the movement international from the beginning.

We have before us an object lesson of great value. When the Woman's Christian Temperance Union was organized it was soon realized that the strength of such a movement must reside in an educated public opinion. To meet this indication abundant literature was distributed and able lecturers provided to arouse public interest. The press was utilized to the utmost possible extent. The most effectual and permanent measure, however, was the introduction of text-books on physiology, written with a special view to inculcating the society's peculiar views concerning alcoholic beverages, into the public schools. By exerting an organized influence on school boards, legislatures and public officials, an influence backed by an appreciable number of political votes, they forced these physiologies into the curriculums of a large proportion of our public schools. Few publishers of school books could now afford to risk the boycott on all their publications that might follow their issue of a text-book on physiology which differed in its treatment of the effects of alcohol from the standards prescribed by the W. C. T. U.

What has been accomplished by an organization whose object is almost an impossibility, an object, moreover, that is hotly opposed by perhaps a majority of mankind, may surely be equaled by a similarly organized body whose object will meet with universal sympathy and approval; for every one must approve of an effort to banish disease and suffering.

Assuming, then, that the object is worthy, and within the bounds of possibility, the next question is, what step should be taken for its accomplishment? It seems to the writer that this Association should appoint a special committee to investigate the matter, inquire into all the possibilities, and report at the next session. This committee should be instructed to decide whether it would be better to create a special bureau within the American Medical Association, having international connection with similar bureaus to be created by the national medical organizations of other countries in order to unify the work; or to organize an independent association under some such title as "The International Sanitary Union," to which all sympathizers, male or female, young or old, lay or professional, would be eligible as members, making it a popular movement from the beginning. In case the former plan is preferred, some kind of membership should be provided for the laity. The church, the educational associations, and, above all, the boundless influence of woman, must be enlisted if success is to be assured.

The three indispensable conditions are: (1) International sanitary organization; (2) international sanitary education; (3) international sanitary legislation. Organization, though the first necessity, is merely a means to the great end, enlightenment.

The root of the whole matter is education. Organization can provide lecturers, newspaper articles, essays, pamphlets, societies, badges and all the paraphernalia for rousing public interest in every civilized land; but far more powerful in its effects would be a chapter on

"The Prevention of Disease" in every school text-book on physiology, in every printed language the world over. In every school grade, from the lowest to the highest, the plain, untechnical statement of the facts would instill into the minds of rising generations the principles that would insure intelligent coöperation with all our efforts for the benefit of humanity.

All this literature for text-books, whether in English, French, German, Spanish, Italian, Russian or Japanese, should bear the stamp of their national medical organizations, and would, therefore, be authoritative. Educated thus from early youth in the simpler and fundamental truths of pathology, the coming generations would be armed against fallacious theories of disease, to say nothing of the effect such enlightenment would have on the fads continually springing up to impose on the people. One who is posted concerning the Klebs-Loeffler bacillus and its toxin, will hardly be tempted to rely on prayer alone for the rescue of a child stricken with diphtheria.

Meanwhile there is no necessity to wait for another session before beginning the work. The seed must be cast on the waters with a liberal hand, and the sooner the better. The officers of the committee to be appointed, or at least the secretary, should be provided with sufficient funds to enable them to enter into correspondence with national medical organizations in other lands, and to distribute appropriate literature among the clergy and prominent educators. Sample literature, proposed to be inserted in text-books, for the different school grades, should be submitted to prominent educators for suggestions or approval. Our publishing facilities at Chicago will enable us to do most of the necessary printing at nominal cost. The daily press should be judiciously used to arouse and maintain the interest of the public, and the ground so carefully and thoroughly prepared that when, at our next meeting, the final form and title of the effort is accepted and announced, the people will be ripe for action.

The effort is a noble one, worthy of the grand organization under whose auspices the writer hopes to see it inaugurated. Perhaps there may be opposition, though it is hard to say why there should be; but the right is greater than any man, however exalted, and will surely prevail. Sooner or later, the conditions herein suggested will be put into effective operation. There is not a single reason why the first step should not be taken at this session of the Association. In twenty years from now we will be no more ready for that first step than we are to-day. If we take it now, twenty years will find us far on the road to the goal, with some diseases eradicated, some diminished, and all under control; with a citizenship too enlightened to be duped by the Eddys and Dowies, too wise to allow helpless or careless sufferers to scatter broadcast the seeds of death. When preventive medicine has accomplished this task typhoid will be no more, malaria a curiosity, yellow fever a matter only of history, and the few accidental consumptives will bask in comfort in government sanatoriums among the sheltered valleys of the Rocky Mountains; while mankind at large will no longer look with dread on three-score and ten years, but will hopefully regard the century mark as about the proper thing. Let no thinking man dismiss this matter as visionary and impracticable. The necessary steps are plain and possible, and will inevitably lead to success if we rise to the level of our opportunity, and earnestly, without haste and without rest, pursue this, the true and final goal of preventive medicine.

This paper is brief because it deals only with fundamental principles. Matters of detail are hardly mentioned. The amount of ground to be covered at the beginning, whether the germs of one, two or three diseases; the varieties of appeal required, some for the scientific, others for the uneducated but practical, and still others for the enthusiasts, all these and many more matters are left for the consideration of the men into whose hands the subject may be confided. The field is wide. There is work for a lifetime. But to what loftier, nobler cause could a man consecrate his powers? No other profession or calling can vie with that of medicine in altruistic devotion to the welfare of humanity. This is the summit of our efforts, the *ne plus ultra* beyond which there lies no further possibility. Let us secure to our Association the glory of the attempt.

SPECIAL INFLUENCES OF THE HIGH ALTITUDES ON THE NOSE AND THROAT.*

S. EDWIN SOLLY, M.D.
COLORADO SPRINGS, COLO.

The subject has, unfortunately, to be considered largely from the standpoint of hypothesis and theory, as at present the facts do not admit of absolute proof. Personally, as a physician without numerous hospital cases to study or a physiologic laboratory to experiment in, I find it impossible to prove the truth of the theories I may entertain in this matter. Though my opportunities for observing these phenomena have been comparatively few at any one time, they have extended over some twenty-eight years of practice in Colorado, and, therefore, have the value of single spies, though they can not have the weight of battalions.

In rhinologic practice in Colorado one is struck with the fact that patients arriving from sea level often complain of nasal symptoms of which they had not been conscious at home. The reasons for this undoubted fact appear to me as follows: In the first place, the altitude causes a marked reduction of atmospheric pressure on all parts of the body, and consequently a greater fullness of the blood vessels of the skin and of the mucous membranes which are exposed to the air. As a result, there is a physiologic congestion of the blood vessels of the nasal cavities, especially of the erectile tissue of the turbinate bodies. Under these conditions it often happens that when a person is transported from sea level to a high altitude, in whom there exists some narrowing of the nasal passages, due to the presence of a septal deflection or spur, or to an hypertrophied turbinate, or a neoplasm, that the increase of the stenosis caused by this physiologic engorgement of the proximate tissues makes him conscious of a nasal deficiency, of which he may have been previously entirely ignorant. This person then feels his nose stopped up and perhaps suffers also from the induced nasal pressure and so passes under the observation of the rhinologist.

As a consequence of this stenosis there is produced a local suction effect as the air passes in and out. While the entire corporeal surface is placed as it were under a cupping glass, the area of stenosis is under a limited but much more powerful cupping glass.

Thus occur local conditions which establish a catarrh, unless the equalization of the general blood pressure, which takes place in a few weeks, that is, after accli-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

matization is established, causes a sufficient subsidence of the local turgescence, or unless relief is effected by treatment. But if the catarrh is unchecked there will ensue a complete and permanent stenosis from a chronic inflammation and enlargement of the proximate turbinate body.

Thus far we have dealt only with the influence of the rarefaction of the air, but there are other influences. The air at an altitude is not only rarefied, but it is exceedingly dry, so that the nasal mucous membrane is called on to yield up moisture to it much more largely and rapidly than at sea level. Consequently the normal mucoid fluid, which should bathe and lubricate the nasal tract, becomes inspissated, forming crusts on the surface and so giving rise to further obstruction, and culture mediums for germs are established. Thus pus is formed and ulcerations appear.

With the dryness of the air comes dust; not dirty but irritating dust, largely composed of minute sharp particles of granitic detritus, of mica, etc. This increases the local inflammation.

Another climatic factor always present in high climates is the wide range and the rapid changes of temperature between day and night, and between sunshine and shadow. In most localities there is also a constant movement of air and shifting of the wind, and on exposed plateaus or in mountain passes, high winds. Owing to the stenosis of one nostril brought about in this way, there develops a hypertrophic catarrh of the other nostril as a result of its having to work double tides.

Behind the influence of the climate on the circulation and exosmosis of the nasal mucous membrane, there is its direct one on the nervous supply of the nose. In the first place the climate stimulates the energy of the whole nervous system and so makes the nasal nervous mechanism more normal and more active, and also more sensitive in its response to stimuli. The overwork and fatigue brought about by the ineffectual efforts to overcome the physiologic and pathologic conditions described, result in more or less vasomotor paralysis, thus the temporary congestion becomes chronic and is greater than before. As a consequence of the resulting nasal stenosis, mouth breathing and catarrh of the nasopharyngeal and laryngeal membranes usually develop.

We have briefly dwelt on the injurious influences of the climate on certain pathologic conditions. Now, let us consider what can be done to mitigate them. Topical treatment by sprays, ointments or direct applications to modify the local congestions may in slight cases remove them, but generally such remedies are only of temporary benefit. Cauterization of a turbinate may sometimes be effective, but in many cases permanent relief will only come after surgical procedure has removed the structural causes of the stenosis.

When the catarrhal change in the membrane is slight after operation the catarrh will disappear, but when it is extreme, the cases improve much more rapidly and surely in a more moist atmosphere and on a lower level. Such cases after a time may return to the high ground and keep well.

In most cases in which there are local causes for a catarrh, there are also systemic disorders which aggravate it. When these disorders are of a nature which a high climate tends to relieve, there is naturally a more rapid and sure cure of the catarrh after appropriate local measures have been carried out, than would have ensued from similar local treatment at sea level.

Atrophic rhinitis is, in my opinion, usually made worse by a high climate, in which view I have the support of my colleague, Dr. Gildea, but, on the other hand, so high an authority as Dr. Levy takes the opposite view. Undoubtedly, the victims of this disease are often benefited in their general health by the tonic effects of the climate. But it stands to reason that with their wide open noses the dry rarefied air taxes to the utmost their defective capacity for moistening and warming the incoming air and far more than does a moist atmosphere with a high barometric pressure.

I have also observed that those cases which have previously had portions of the turbinates or septum too freely removed, suffer much more discomfort in high than in low climates.

It has been said that Colorado cures those who come with catarrh and induces it in those who come without it. The apparent reason for this statement is that undoubtedly a flabby weeping nasal membrane is much benefited, while a dry, irritable membrane suffers because its secretion which was sufficient at sea level is too scanty in a high climate.

CONCLUSIONS.

To sum up it may be said that:

1. Surgical measures are often demanded at an altitude in cases which had previously gotten along comfortably without it at sea level.

2. The results of such procedure are at least as satisfactory as elsewhere, but more than usual care must be taken to save all secreting tissue.

3. The local symptoms of atrophic rhinitis are aggravated, though the constitutional conditions are often markedly improved.

4. The moist form of hypertrophic rhinitis is much improved.

In disease of the accessory sinuses, if the appropriate relief is given, the affected surfaces dry up and heal more rapidly and surely than at sea level. In this respect the result is the same as is well known to be the case in the healing of other wounds and ulcerations.

With regard to surgical cases treated at an altitude, nasal or otherwise, it is undoubtedly true that they do better and require less postoperative care than at a low level.

There appears also to be an absence of the danger of infection to the wounds inflicted on tuberculous cases, which is usually so much dreaded elsewhere.

Thus far our discussion has been limited to the influence of altitude on the nose. We will now briefly consider its effects on the throat. In the first place it may be said that in most instances what affects the nose also affects the throat. This applies to disorders whether of local or systemic origin. The limits of this paper do not permit a full discussion of the influence of the climate on tubercular laryngitis, but it may be here stated that the experience of the writer and most of his colleagues is that it is decidedly favorable. Of course, it is recognized that tubercular laryngitis is for the most part an expression of a tendency of the tuberculosis to spread, and that the great majority of the cases die from their pulmonary tuberculosis, yet the narrow margin of recoveries is less narrow when the cases are treated in a high altitude, and that local treatment is much more successful than at sea level.

The tonic and stimulating effects of the climate, both direct and indirect, are as markedly beneficial to local

and general anemia as they are irritating to plethoric and hyperemic conditions.

DISCUSSION.

Dr. Melville Black, Denver.—I would be inclined to consider the dryness of the climate the most important in its effects. In the beginning the immediate effect is very largely that of reduced atmospheric pressure, producing temporarily a sort of vasomotor paresis; at least the patient has the symptoms of such in a mild form. This passes off after a few weeks. Our relative humidity is something like 49 per cent. The relative humidity in New York is 75 per cent.; San Francisco, 75 per cent.; Portland, Ore., 80 per cent. So that you see the relative humidity at sea level is about double that of Colorado. When we say the average is 49 per cent., that does not represent the humidity as it usually is. The morning and evening humidity is greater than that during the day, but it brings up the figures of the statistics. At noon it probably would usually run not higher than 20 or 25 per cent. Therefore, in Colorado the nose has to do fully double the work required at sea level in order to bring the inspired air up to a point of saturation. The prevalent complaint of all of our residents is of dryness. When we come down to New Orleans we find that our noses feel unusually comfortable. I think Dr. Solly will bear me out in this. We have hypertrophic conditions as the result of the increased function, followed by a form of mild sclerosis. Septal deviations and other conditions, which would naturally contribute to make it more impossible for the nose to perform its normal functions, require operation more in Colorado than elsewhere. I do not think Dr. Solly or myself would like the impression to go out that we have a climate that is particularly prolific in the production of "catarrh." I have never seen anything serious from it. I do not believe our climate will help dry nose and middle-ear conditions. When patients are to be sent to Colorado for otitis media, catarrhalis chronica these factors should be considered.

Dr. H. W. Loeb, St. Louis—One feature of the paper is of especial moment to me, coming so soon after the rather unequivocal statement made by Levy at Washington last year, that laryngeal tuberculosis is improved in Colorado. The fact that the patient has laryngeal tuberculosis should not militate against sending him to Colorado. Until last year my practice has been to tell such patients that nothing in the way of hope is offered by Colorado or any other climate after the larynx is affected. This coincides with what some of the German authors say on the matter. But since last year it has been my practice to send the cases of laryngeal tuberculosis to Colorado. The Colorado members of our specialty feel that in Colorado there is some hope for these patients.

Dr. Sargent F. Snow, Syracuse, N. Y.—I now find it unnecessary to treat my cases of laryngeal tuberculosis locally if the pulmonary conditions are urgent, but immediately send them where they get dry pure air. If they are in an early stage, so far as the pulmonary condition is concerned, I treat them locally for a while. I have sent to the Adirondacks five cases in which there were marked ulcerations and infiltrations of the larynx, and they have all healed up perfectly and have good restoration of function. In cases with the peculiar hard spasmodic cough, an examination of the vault of the pharynx will show a granulated condition, sometimes an intensely irritated area, on which crusts form, and if this be treated with applications of nitrate of silver, 40 grs. to the ounce, we give them very great relief. But I do not think we are justified in keeping these patients in their home environments for local treatment. Get them as soon as possible into higher and drier climates. I feel sure that 2,000 feet is a better altitude than 500, but I have had only a limited experience with altitudes greater than 2,000 feet.

Dr. S. E. Solly, Colorado Springs—We are very firmly impressed by the remarkable results we get in Colorado, particularly when we have to use operative measures in the larynx and throat, which we find can be carried on there with much less risk and with better results than are usually obtained at sea level. Moreover, there is apparently much less danger of a laryngeal wound becoming infected by tuberculous sputum passing over it.

ARRESTED TUBERCULOSIS.

SUBSEQUENT HISTORIES OF SEVENTY-NINE ARRESTED CASES TREATED AT THE SHARON SANITARIUM FROM 1891 TO 1902.*

VINCENT Y. BOWDITCH, M.D.

Medical Director, Sharon Sanitarium; Attending Physician, State Sanatorium, Rutland, Mass.; Consulting Physician, Boston City Hospital and New England Hospital for Women and Children.

BOSTON.

Four years ago I had the pleasure of giving the subsequent histories of thirty-four "arrested" cases of pulmonary disease treated at the Sharon Sanitarium from 1891 up to 1899.[1] I will not apologize for bringing up the subject again, for all will agree that it is the after-histories of such cases which prove the efficacy or otherwise of methods which are now so prominently before the public.

Let me again cite the fact that these results have been obtained in a climate thought to be most unfavorable for consumptives, not far from the sea-coast and at the insignificant altitude of between 200 and 300 feet only above sea-level. In these latter particulars the Sharon Sanitarium was for several years unique. During recent years, Dr. Millet's sanatorium at East Bridgewater has been built with similar conditions, although it is intended for patients who are of a more well-to-do class than those at Sharon, where only patients of limited means are received. The State Sanatorium at Rutland, opened in 1898, has an elevation of 1,100 feet, and is fifty miles from the sea.

Again let me refer to my use, up to the present time, of the term "arrested," which has included all those cases in which abnormal outward symptoms have disappeared, many of them having justified the more favorable terms used by some authorities, "apparently cured" or "cured," at the time of discharge.

Since my last paper, the institution has been enlarged from the capacity of nine to twenty-one beds.

The total number of cases discharged since the opening of the institution in February, 1891, up to April 1, 1902, is 182. Five of these remained but a few days, and were not under treatment, and 13 were cases of asthma or simple bronchitis; therefore, 18 are not considered in the results.

In tabulating the remaining 164 cases which are considered, I have allowed a year to elapse since the last one of the number was discharged.

Seventy-nine of these 164 cases were recorded as "arrested," a percentage of 48.17+ of all the phthisical cases.

Of these 79 cases, which include those mentioned in my report of four years ago, 12, or 15.2 per cent., have died since leaving the institution, after varying intervals of comparative health.

In my previous report, 6 out of the 34 "arrested" cases had died. In that paper, I gave the probable reasons for the relapse and explained that in one the cause of death was from shock during some uterine operation, no trace of previous pulmonary disease having been noticed by the attending physician previous to the patient's

* Read before the American Climatological Association.

death. In the other 5 a return to unhygienic surroundings had brought about a relapse in patients who had on entrance marked symptoms of disease varying in extent and severity, and in whom any arrest of disease was thought on entrance to be improbable.

Since that time two more of those then reported (Nos. 18 and 27 of the following list) have died, both of whom had had well-marked disease in one or both lungs before entrance, and in whom the arrest was a remarkable proof of the efficacy of sanitarium treatment. One of these returned to a life of drudgery with four small children and no servant to assist her. She remained very well for two years at least, but finally broke down and died five years after discharge. The other, all of whose family had died of phthisis, remained in excellent health without any abnormal symptoms, in spite of hard work in Boston and in Florida for three years. After marriage she broke down again. Her cough returned. She again entered the sanitarium, where her cough again ceased completely for several months, but in consequence of a severe cold last autumn she had another relapse, failed rapidly, and died this winter in Florida.

The histories of the remaining 4 of the 12 who have died are significant. Only one (No. 45 of the following list) was what can be called an "incipient" case, with râles at one apex, complicated with severe mitral disease which rendered the treatment more difficult. An arrest of the cough and expectoration was accomplished, but on return to a damp, unhealthy house, the patient relapsed, rapidly failed, and died not long afterward. Two others (Nos. 51 and 52) had well-marked symptoms in both lungs, but remained two or three months in the sanitarium without cough or other abnormal symptom, and for months after discharge were in excellent health. For reasons not fully explained, however, both these cases suddenly developed serious symptoms again, and died one and two years after leaving the sanitarium. The remaining case (No. 61) had far-advanced disease in one lung. After a stay of 4¾ months at Sharon she left without any abnormal outward symptom, looking perfectly well, and remained so for several months; but a return to objectionable methods of life in the city brought on a relapse, and she died in 1902.

Of the remaining 67 "arrested" cases, excellent accounts are received with only one or two exceptions, the former having sent no report at all of recent years. She was known to be feeling well at last accounts. The latter, a case of fairly well-marked disease, has failed in strength, and doubtless will sooner or later succumb to the disease. The majority write enthusiastically of their good health, some of them having left the sanitarium ten years ago. All are employed in their homes or in occupations which, as a rule, allow them to be out of doors more than before.

It would be impossible, of course, to give each case in detail to you here. A tabulation will be made with the published paper whereby one may judge fairly well for himself of the results claimed. For the laborious and careful preparation of these tables I am greatly indebted to Dr. Walter A. Griffin, the resident physician at the sanitarium.

I am aware that some of the cases could be possibly challenged from the fact that the presence of bacilli could not be proved and because the tuberculin test had not been tried. In answer I can only say that only those cases have been taken which experience teaches us usually develop later more definite signs of disease under unfavorable conditions. I wish it were in my power to bring before you some of these patients, now apparently well, who were in the sanitarium formerly. Their presence and aspect would speak more eloquently to you than my mere statements of what can be done. I must content myself, however, by citing a single case as an example.

One woman (H. Q.), a domestic, was sent to Sharon from the Massachusetts General Hospital out-patient department in 1893, with bacilli in her sputa and having evidences of trouble in the right lung. She had previously been told by a physician in Ireland that she had consumption and could not live. After a stay of 14 months, she left the institution, a magnificent specimen of health, her cough having ceased several months before. She has remained perfectly well since (9 years), having been actively employed as a domestic in

Boston and the suburbs, and lately wrote that she was never better in her life. I could cite several other cases which differ only in minor details, but this will serve as an example of what can be done not far from home in a changeable, harsh climate, at an altitude not far above sea-level.

In citing these cases I do not wish to be misunderstood. I have never been one of those who believe because of the success of sanatorium treatment in a large percentage of cases in a climate like that of New England, that it is, therefore, unnecessary for any one to seek another climate. I believe, as I have stated elsewhere, that in more salubrious climates better results can be obtained by this method than with us; but for the hundreds and thousands of sufferers who for various reasons can not go far from home, institutions like Sharon, Rutland and that of Dr. Millet at East Bridgewater are of inestimable value. I claim, moreover, after twelve years' observation, that it has been shown that it is not always necessary to send people far away in order to get well.

To keep the subsequent histories of sanitarium patients before use is, therefore, of ever-increasing interest, for by so doing we learn the true value of what may have been of the nature of an experiment at the outset.

What may we learn by studying these cases? Not only that more can be done near our homes by these methods than has been thought possible in former years, but that a large percentage of patients in whom the disease is arrested can remain well under ordinary conditions of life, especially if attention is paid to proper methods of hygiene. On the contrary, we learn that a return to unhealthful conditions is in the majority of cases usually, although not always, followed by relapse and a fatal result.

It is made more evident, too, which has been often said, but it can not be said too often, that in order to obtain the best results, patients should be placed under treatment during the earliest possible manifestations of trouble, notwithstanding the fact that in many cases of well-marked disease success has been attained.

In this paper I have confined myself solely to the histories of "arrested" cases, and have said nothing of the large percentage of those who have so much improved that they have become wage-earners again and a comfort to their families, even though they may not have wholly recovered their health. Neither have I touched on the educational influence which such institutions have on the community, a fact which I believe to be of as great importance as the benefit to the individuals themselves who enter for treatment. These points must be left, however, for other times and places.

As to methods of treatment and details of management at Sharon, they can not be enlarged on here. Suffice it to say they are what are employed in all well-regulated sanatoria of this nature. It may be said, however, that within the past three years the fresh-air treatment has been pushed to its utmost limit, even in the coldest weather, the results being even more satisfactory than in the earlier years of the sanitarium. Elsewhere[2] I have touched on this special point.

In conclusion, let me say that it is my belief that these methods will be found to be efficacious in all forms of tuberculosis, whether of medical or surgical nature. Surgeons are already seriously discussing the wisdom of fresh-air treatment in tubercular joint disease, and if we reason by analogy I see no reasonable ground for doubt that such cases will find it at least an adjunct as powerful for recovery as it is in pulmonary disease.

THE RED-LIGHT TREATMENT OF SMALLPOX.

NIELS R. FINSEN.
COPENHAGEN, DENMARK.

In a former issue of THE JOURNAL[1] there appeared an article by Dr. J. F. Schamberg, entitled "An Examination into the Claims of the Red-Light Treatment of Smallpox." He criticises the treatment: 1, Because I called it a new one; 2, because he considers my theoretical views concerning smallpox and light to be wrong, and 3, because he is of the opinion that the red-light method has proved inefficacious, and that the good results in all former experiments may have been due to

2. Origin and Growth of Sanatoria for Tuberculosis in Massachusetts. Jour. of Tuberculosis, vol. v, No. 2, April, 1903.

1. May 2, 1903, page 1183.

other factors; and he further suggests that the cases so treated were probably so mild in type that they would have escaped suppuration without the red-light treatment.

I. "THE RED-LIGHT TREATMENT IS NOT NEW."

I am surprised that Dr. Schamberg should consider the modern red-light treatment to be the same as the one employed in the middle ages by Gaddesden and others. The modern red-light treatment is a negative treatment, its object being to prevent the chemical rays of daylight or light from acting injuriously on the patient. Whether this be obtained by leaving the patient in entire darkness or in red light is in itself quite immaterial. I have recommended red light because it is more agreeable than complete darkness, while it is of the same value in the treatment, but I have no doubt that either dark-yellow or dark-green curtains might be used, provided only that they are so dark as to exclude the chemical rays.

In my papers on the subject I have used the expression "treatment of smallpox by exclusion of the chemical rays of daylight" more frequently than that of "red-light treatment," thus avoiding the danger of mistake as to any similitude with Gaddesden's treatment. The latter term, however, has the advantage of being shorter and more easily understood, especially by those who have some idea of photography and of the photographer's red-room. Gaddesden's treatment was a positive one, and consisted in surrounding the patient with all sorts of red things, red pictures on the walls, red balls in the patient's bed, etc. Dr. Schamberg himself quotes the following description of John of Gaddesden's way of treating the Prince of Wales, who was "treated for smallpox by being put into a bed surrounded with red hangings, covered with red blankets and a red counterpane, gargling his throat with mulberry wine and sucking the red juice of pomegranates." At that time it did not occur to them to shut out the light from the sick-room. Their explanation of this peculiar treatment was that the red articles should irritate the blood just as a bull is irritated by a red cloth, thus producing a more pronounced erythema, that is, forcing all the "bad matter" to get out."[2]

The object of the modern "red-light" treatment is just the opposite, viz., to make the exanthem less pronounced. When, in spite of all this, Dr. Schamberg states that the modern red-light treatment is not new, but the same as that of the middle ages, I do not agree with him.

II. "MY THEORIES ARE NOT CORRECT."

Considering the fact that the author of this criticism has so faulty an understanding of the method that he considers the smallpox treatment of the middle ages as identical with the modern treatment, that of excluding the chemical rays of light, I think that it would be useless to discuss theories with him.

III. "THE RED-LIGHT TREATMENT OF SMALLPOX IS INEFFICACIOUS, AND THE GOOD RESULTS, AS SHOWN BY ALL FORMER EXPERIMENTS, ARE DUE TO OTHER FACTORS."

The above verdict on the results obtained and published by a score of well-known physicians skilled in the treatment of smallpox, is pronounced by Dr. Schamberg, on the basis of an experiment made by himself with two patients. Although this number, as admitted by Dr. Schamberg himself, is small indeed, I might not have taken exception to it had not it clearly appeared that both patients were put under treatment too late, and the treatment did not fulfill the conditions I have fixed as indispensable. I therefore can not help thinking that Dr. Schamberg would have acted more wisely had he deferred the publication of his opinion until he had gone into the matter more thoroughly.

Dr. Schamberg says in his paper that his two patients were placed in the red-light room "about the third day of the eruption"; in other words, on the seventh day of the disease.[3] In my paper in the *British Medical Journal*[4] I say: "When the patients come under treatment early enough, before the fourth or fifth day of the disease, suppuration of the vesicles—even in unvaccinated persons and in cases of confluent smallpox—will be avoided, one exception out of about 70," and, further, in the same paper, "should the patient come under treatment after the fifth day of the disease, it is uncertain whether the suppuration can be avoided. Sometimes this is the case, sometimes not."

Now, as Dr. Schamberg's two patients were unvaccinated, delirious men, furnishing particularly severe cases with confluent pustules, it was particularly unfortunate that they did not come under the treatment until so late, and I am not surprised that suppuration occurred.

Of the many medical men who have tried this treatment and who have written about it, Dr. Schamberg is, so far as I know, the only one who disparages it on the ground of bad results. I have no doubt that he, too, will become a warm sympathizer in time.

THE CONDITIONS INDISPENSABLE TO SUCCESS.

In order to prevent future attacks, based on erroneous experiments with this method, I repeat that two conditions are absolutely indispensable if good results shall be obtained, viz.: 1, As stated above, the patient should be placed under treatment sufficiently early, and 2, the chemical rays of daylight should be absolutely shut out. The efficiency of the method is so certain that in case suppuration should occur in a patient who was placed under the treatment in proper time, the first thing to be thought of is that from want of care either on the part of the patient or of the nurse daylight may have penetrated. Therefore, before the method can justly be declared a failure the thoroughness with which it is carried out should be tested by exposing photographic plates or sensitized paper as a means of control in different places in the sick-room. If these photographic plates show the influence of white light the technic of the treatment has been imperfect. A few of those who have applied the method have at the same time treated the patient by other remedies as well. Such a course is objectionable for scientific purposes, as it is then impossible to decide which agency is responsible for the results. In order to give the experiments decisive scientific value they should be carried out under strict control and the patient placed under the treatment in proper time.

Remarkable Case of Contagion of Syphilis.—A pedestrian was accidentally hit on the nose by the tip of the whip of a passing teamster. A typical chancre developed at the point of the slight excoriation and investigation revealed that the teamster had syphilitic lesions in his mouth and was in the habit of nibbling his whiplash. This occurrence was reported by Dr. Melot in a French exchange.

Clinical Report.

A CASE OF EMPYEMA OF THE FRONTAL SINUS.*

C. A. THIGPEN, M.D.
MONTGOMERY, ALA.

J. B. C., aged 38 years, consulted me for headache and vertigo.

History.—Thirteen years ago he had an attack of la grippe which was accompanied by much constitutional disturbance. During the time of his confinement he had fever and suffered much from headache, which was intolerable at times. He also stated that there was a discharge from the left nostril which has persisted since, except at times when he would "take cold" the discharge would cease, and his headache would become more intense, with much vertigo, nausea and mental stupor; these symptoms subsiding "when the cold would break" with a profuse discharge from the nose.

With this incomplete history of thirteen years' suffering I began my examination of the patient. His physical appearance was one of anemia and emaciation. The left frontal region was more prominent than the right, and the left eye was pushed down and out, and there was diplopia.

Examination of Nose.—Right nostril was clear and free from disease. Left nostril, there were several large polyps which occluded the nostril, and these were bathed in pus, which filled the entire cavity. With this condition of things I at once concluded that he had empyema of the ethmoidal, frontal and maxillary sinuses on the left side and advised operation, which he refused at that time. About two weeks later, however, he returned to me in great distress, and requested me to perform the operation. He was accordingly placed in the hospital and the usual preparations made.

Operation.—Preliminary to opening the frontal sinus I removed the polyps with the middle turbinate and curetted and broke up the anterior ethmoidal cells. The frontal sinus was then opened by making a median vertical incision, which was joined by one at right angles just above the brow. I selected the highest point possible in order that I might drill freely downward and backward into the nose. On opening the cavity a great quantity of pus escaped in spurts, with the pulsations of the heart. There were also some small polyps and granulations, and on removing these with my curette I came in contact with a yielding surface, which pulsated. The opening in the bone was enlarged, and I found myself in a large cavity, the anterior wall of which was formed by the frontal bone and the posterior wall by the dura and the brain. Around the border of this cavity there were firm adhesions between the dura and the bone. There was a firm and strong septum which separated this cavity from the opposite side. The dura was much thickened and covered with granulations. These were gently curetted away and the cavity irrigated with saline solution. No difficulty was experienced in making a large opening into the nose, through which was drawn a large piece of gauze. The cavity was loosely packed and the external opening closed, except at the lower inner angle, the head was bandaged and the patient placed in bed. The subsequent course of the case was uneventful, fever and pain disappeared, as well as the vertigo, and the mind became much clearer. After two weeks the patient was allowed to return to his home, with instructions how to look after himself. Reports from time to time were favorable, and three months later, when he returned to see me, I was surprised to find him entirely well, having gained much in weight. He was the picture of health. Careful examination failed to find any cavity which had become obliterated.

I report this case because of the unusual conditions found at the operation, the absence of the posterior wall of the sinus, pressure on frontal lobe, with mental impairment. Whether the absence of the posterior wall of the cavity was an anatomic anomaly or the result of breaking down due to prolonged suppuration, I am not able to say, but I rather incline to the latter opinion. Ingals reports one case somewhat similar in which there was an absence of the septum and posterior walls of both cavities. The same author also cites a case of Gibson's where there was an absence of the posterior wall on right side, the patient dying of septic meningitis.

New Instrument.

AN IMPROVED MERCURY MANOMETER.

C. C. GUTHRIE, S.B., M.D.
(From the Hull Physiological Laboratory, University of Chicago.)
CHICAGO.

The accompanying figure illustrates the main features of a mercury manometer which I have found more convenient than the ordinary type for blood-pressure work.

The float A and cap B are made of aluminum and the piston C and the guide rod D of polished or nickel-plated steel. The wood base is cut out in such a manner as to protect the ends of the tubes E and F. E is connected with a three-way canula, which is in communication with the pressure bottle and blood vessel. In filling or washing out the manometer from the pressure bottle with the solution used to prevent clotting (I employ 2 per cent. sodium citrate), F, which is fused into the manometer tube E, about 1 cm. above the level of the mercury at zero pressure, serves as an outflow tube. Of course, when a pressure tracing is being taken, the rubber tube on F is closed by a pinch-cock. The perpendicular guide rod which keeps the writing point against the drum is movable around a horizontal axis and is thus easily adjusted, and as it is attached to the manometer base, it does not interfere with other apparatus on the manometer stand.

Social Functions of the County Society.—The *Iowa Medical Journal* commends the spending of time occasionally in social functions where physicians can meet at least in a semi-leisure way, where they find that each of them is well worth cultivating—for the physician, however scientific he may be, is more than a scientist; he is a man, he is earnest, he is honest, he is broad, he is deep, he has heart interests, he has sympathies. He appreciates all those things that go to make up the best that is in the world and has to consider all those things that go to make up the worst of the world.

THE ETIOLOGY OF ACUTE ARTICULAR RHEUMATISM.

It has long been held that acute articular rheumatism is an infectious disease, but no positive proof has been furnished. The basis for this belief includes the following clinical observations: 1, Rheumatic fever occurs in epidemics; 2, there is a great constancy in the seasonal variations; 3, there is a striking similarity of the symptoms of rheumatic fever to those of septic infections. Bacteriologic investigations of this disease have not been wanting, but the results are somewhat confusing. As early as 10 and 12 years ago several investigators reported the finding of staphylococci, streptococci and diplococci in the excrescences in the heart valves and in other organs of patients who succumbed to this disease. Among the earlier investigators we find four who have isolated staphylococci, five who isolated streptococci and six who found diplococci.

In 1897 Achalme found an anaërobic bacillus in the heart's blood and in other organs of patients who died from acute rheumatism. This work was confirmed by several other French investigators, but more recently discredit has been thrown on it by Achalme himself.

In 1899 these investigations received a new impetus through the work of Wassermann. He reported a case of postrheumatic chorea, from the heart's blood of which he isolated a streptococcus. This organism appeared as a diplococcus in the tissues, but formed chains on artificial media. It grows best in alkaline media. When injected into animals it produces fever, arthritis and death. Wassermann believes this organism to be the cause of rheumatism, and differentiates it from other streptococci by the facts that it grows best in alkaline media and that it produces arthritis when injected into animals. Meyer described a similar organism which he isolated from the tonsils of patients suffering from acute rheumatism. His cultures from the blood and joint punctures gave negative results, but nevertheless he concludes that his organism is the cause of rheumatism.

These views were strongly opposed by Singer and by Menzer, both of whom have isolated streptococci from cases of acute rheumatism. Singer, who seems to have done more work on this disease than any other investigator, believes that it may be caused by any of the pyogenic cocci. In over 100 cases that he examined with some 30 positive results he found the *Streptococcus pyogenes* most frequently, and occasionally the *Staphylococcus pyogenes aureus*. Both he and Menzer point out that joint changes have been produced in animals with staphylococci and with streptococci which were isolated from the throats of scarlet fever patients, when these organisms were injected into the circulation. They also call attention to the fact that some of the ordinary streptococci grow best in alkaline media, as was shown by Lingelsheim. It is also well known that streptococci may be isolated from the throats of patients not suffering from rheumatism and of healthy persons. Hence not much stress can be laid on the work of Meyer.

In 1900 Paine and Poynton reported 8 cases from which they isolated a diplococcus. This organism also produces arthritis, pericarditis, endocarditis, wasting and death when injected into animals. It grows best in acid media. These investigators believe their organism to be a cause of acute rheumatism and to be identical with that described by Wassermann. It is interesting to note here that this organism grows best in acid media, while Wassermann attempts to differentiate his organism from other streptococci by the fact that it grows best in alkaline media.

Beaton and Walker[1] have recently taken up the study of acute articular rheumatism and have described a diplococcus which grows in chains in artificial media. It grows best in strongly alkaline bouillon and produces large amounts of formic acid. It grows in the filtered cultures of streptococci and hence, according to Marmorck, is not an ordinary streptococcus. They found this organism in the heart's blood after death from chorea, acute rheumatism and endocarditis, and also in the blood and urine of patients before death. When injected into animals it produces fever, wasting, arthritis, pericarditis and endocarditis. They believe this organism to be identical with the one described by Wassermann and to be specific for acute rheumatism. They have proposed for it the name *"Micrococcus rheumaticus."* Culturally, it can not be differentiated from the pyogenic streptococci, but these investigators attempt to differentiate it on the following points: 1, It grows best in alkaline media; 2, it produces arthritis, endocarditis, etc., when injected into animals; 3, it grows in the filtered cultures; 4, it produces large amounts of formic acid. The first two points have already been dealt with, and in regard to the others the following may be said: Streptococci will grow in the filtered cultures if the filtrate does not contain too high a percentage of acid for the organism which is inoculated. All streptococci are said to produce formic acid, and when we consider that the toxin-producing power of these organisms varies within wide limits we would not be surprised to find that the acid-producing power is different under different conditions.

It seems, therefore, that we are not yet justified in speaking of a specific *Micrococcus rheumaticus*. The pyogenic cocci have been repeatedly isolated from the heart valves and blood of patients who succumbed to

1. British Med. Jour., Jan 31 and Sept. 19, 1903.

acute articular rheumatism, chorea and malignant endocarditis, and it would seem as if these organisms do maintain an intimate relationship to the processes usually spoken of as acute articular rheumatism.

BEHRING'S VIEWS ON TUBERCULOSIS.

Behring, who is a good authority on such questions and whose opinion, therefore, carries weight, accepts the view that everyone is slightly tuberculous, but this by no means implies that everyone is or will be affected with pulmonary phthisis. He thinks two things are necessary to produce phthisis: a tuberculous focus and bodily conditions favoring the development of the disorder. He regards the contagion of consumption in adults with grave doubt, holding that it has not yet been demonstrated. Therefore, the predisposition to pulmonary infection is not in exposure to infection which is shared by all more or less, but in the conditions of life. The more probable cause is the awakening of a latent focus into activity on account of defects of nutrition or from impairment of health.

Leaving out of consideration for the present his opinions as to the early infantile origin of pulmonary phthisis, his views are in a measure somewhat comforting. These views should not encourage us to neglect reasonable precautions for self-protection, but they do oppose the pessimistic views held by some modern alarmists. Behring's opinions also have this in their favor; they harmonize with the great decrease of tuberculosis under better modern conditions of living which implies that the bodily resistance, given a fair chance, will throw off the disease. As we have often said, it seems probable that in time consumption may be a comparatively negligible affair and that tuberculous infection of itself is not so much to be feared under ordinary hygienic conditions of life. It is only when reinforced by other pathologic infections that it develops into the disease so much dreaded. The possible, if not even probable, hope of an immunizing serum against tuberculosis is also to be considered. The results of Behring's experiments on the lower animals, as well as the earlier ones of Trudeau and De Schweinitz, are certainly encouraging, and give us good reason to be hopeful for the future.

While the profession is in a receptive mood for anything scientific and new in regard to tuberculosis, it is not yet prepared to swear by the words of any master, however high he may be in science or in medicine. The result of Behring's utterances, therefore, will be to increase our caution as regards the infant acquirement of tuberculosis and probably not to diminish it as regards its communicability to adults. One thing is certain, however, and that is that bodily resistance to the germ is an important thing. We must build up our defense, while not neglecting active measures to prevent the attacks from the outside. In any case it is well to remember, considering the discrepancies of views held by some authorities whose opinions we can not but respect, that extreme radical opinions in regard to either the dangers or comparative harmlessness of the tubercle germ are out of place. We have to be somewhat selective as regards our views, and it must be with judgment. Another thing is that the evidence shows that the problems of tuberculosis are not to be worked out at once. We are yet in the transition period, and there is much uncertainty before as well as behind us in regard to this particular subject. The report of the British Tuberculosis Commission will be anticipated with interest as probably giving a judicial statement of our present acquisitions, if not more positive data, especially as regards the varying views held as to the dangers of bovine tuberculosis and the liabilities of the human species to its infection.

CHRISTIAN FENGER AS A PATHOLOGIST.

In an address before the Chicago Pathological Society[1] Dr. E. R. Le Count gave an excellent and thorough review of the pathologic work of the late Christian Fenger. It was indeed a happy thought that guided the author in the preparation of this address along the lines indicated in its title; for it was the persistent, laborious study of the fundamental pathologic conditions that gave to Fenger's work as a surgeon and as a teacher of surgery its lasting influence on the development of scientific medicine in this part of the country.

This is hardly the place to review in detail Fenger's remarkable work as pathologist and surgeon. Those who knew him in his lifetime and perchance were fortunate enough to come under his personal influence will find that Dr. Le Count's address in every way gives an adequate and sympathetic presentation of his painstaking methods of work and of the scope of his investigations. To the younger generation of medical men just entering on the scene of professional activity the address is recommended for careful study in order that they may receive stimulus and inspiration from this noble example of untiring work and love of truth that after all were the chief lessons of Fenger's life, for the master-word in medicine is "work." "It is directly responsible for all advances in medicine during the past twenty-five centuries. Laying hold on it, Hippocrates made observation and science the warp and woof of our art. Galen so read its meaning that fifteen centuries stopped thinking and slept until awakened by the *De Fabrica* of Vesalius, which is the very incarnation of the master-word. With its inspiration Harvey gave an impulse to a larger circulation than he wot of, an impulse which we feel to-day. Hunter sounded all its heights and depths, and stands out in our history as one of the great exemplars of its virtues. With it Virchow smote the rock, and the waters of progress gushed out; while in the hands of Pasteur it proved a very talisman to open to

1. Trans. Chicago Path. Society, 1903, vi, 1-20.

us a new heaven in medicine and a new earth in surgery. Not only has it been the touchstone of progress, but it is the measure of success in everyday life."

So writes Osler in one of his helpful and charming addresses. And it was work that made Fenger, at first practically unaided, the leader of scientific medicine in the Northwest for twenty odd years, a period which he himself characterized as a period of uninterrupted progress. It was work that made it possible for him, coming here from a strange country, to say at the close of his career: "It is a satisfaction to me to have done my life-work here, witnessing and taking as best I could a small part in the growth of the West."

GRANTS FOR SCIENTIFIC WORK.

A further result of the small grants given by the American Medical Association to promote scientific research is embodied in the article by Otis and Evans on "The Morphology and Biology of the Parasite from a Case of Systemic Blastomycosis" in The Journal, October 31. Through an unfortunate oversight it was not stated in connection with the title of the article that the work had been promoted by an Association grant. We have referred in the issue of July 4, 1903, to the significance of the case of accidental infection with oidiomycosis from which was recovered the same organism as that described in the exhaustive study of Otis and Evans. It may be recalled that this case, being one of accidental infection from a known source, is to be regarded as an important landmark in the series of observations that have established blastomycosis or oidiomycosis on a firm basis. It was, therefore, doubly desirable that a thorough study of the organism concerned should be made. So far, the small grants offered by the Association have been the means of promoting interesting researches into the nature of streptocolysin[1] and in the field of mold-fungus infections of man. We believe that not the least important result of these grants is the encouragement thus given to young men to develop the spirit of investigation.

OUR PHILIPPINE QUARANTINE SERVICE.

Since we have acquired eastern possessions, with certain responsibilities and risks, it is satisfactory to know that our agents in the Orient are attending to sanitary matters. Plague and cholera have existed in the Philippine Islands for the past year and the latter especially has been a scourge in a large portion of the group. Notwithstanding the fact that we are in almost weekly communication with the islands and that travel back and forth by army transports and otherwise has become very extensive, we do not dread the introduction of cholera into this country because of our confidence that the quarantine authorities in the Philippines are wide-awake. The annual report of the chief quarantine officer for the Philippine Islands for the year ending July 31, 1903, contains some interesting particulars. With the possible exception of the work done at Tor, Egypt, near the southern entrance of the Suez canal, there is probably more disinfection accomplished at Mariveles station, near Manila, than at any other similar one in the world and this, moreover, with labor that speaks a foreign tongue and which has to be educated in every particular. This outlying fortress for public health is certainly doing very creditable work. There have been, it is estimated, about 300,000 cases of cholera in the Philippine Islands during the year covered by the report, and the extent of the disease is attributed largely to the possibilities of easy communication by small native crafts and boats which are hard to oversee throughout so extended a region and under such unfavorable circumstances as exist. A history of some of the epidemics that have entered the island prior to American occupation gives rise to the belief that some of them have entered from the south; therefore, an additional quarantine station has been established at Jolo, in the southern end of the archipelago, which is an important point in the commerce with adjoining Malaysian islands. It is a notable fact that plague has not extended during the year away from the City of Manila; it may be said to be firmly bridled and controlled. There seems to be a cordial co-operation between the public health service and the local boards of health in this matter. Taken altogether, and considering the possibilities of an inefficient or negligent administration of health matters there, we have many reasons to congratulate ourselves. Our commerce with our Oriental possessions is constantly growing, and with more intimate relations the greater will be the need of eternal vigilance as a safeguard for our own communities.

1. The Journal, Oct. 17, 1903.

THE IMPORTANCE OF HEMATOLOGIC INVESTIGATIONS.

The number of those who decry the importance of blood examinations as a diagnostic measure is progressively diminishing, while the number of physicians who include a hematologic investigation among their clinical assets is as progressively increasing. It is not only the enumeration of the erythrocytes and the leukocytes and the estimation of the hemoglobin percentage that are of importance, but also a knowledge of the morphologic characteristics of the dried and stained films is frequently necessary for a satisfactory diagnosis. In some instances, although the blood may show no absolute leukocytosis, stained specimens show a relative leukocytosis of the first importance. In the case recently reported by Kelly[1] of a man who complained of weakness and who presented, on physical examination, slight jaundice, great enlargement of the spleen, moderate enlargement of the liver and leukoderma, a blood examination showed only 9,000 leukocytes. A differential count, however, showed that 98 per cent. of the white cells belonged to the lymphocyte class. Under observation, the leukocytes at different times numbered 6,000, 5,200, 18,200 and 37,600, and always with an increase of lymphocytes (96.5 and 98 per cent.). The patient died in coma. At the necropsy marked enlargement of the lymph nodes, except those of the axillary and the inguinal regions; enlargement of the spleen; gumma and syphilitic cirrhosis of the liver, and lymphadenoid bone marrow were demonstrated. There seems to be a ten-

1. Univ. Pa. Med. Bull., October, 1903. See abst., p. 1230.

dency, among certain observers, to depart from the original division of leukemia into two classes—lymphatic and myelogenous, as made by Ehrlich. To one reading the chapter on leukemia, in the eighth volume of Nothnagel's *Specielle Pathologie und Therapie,* by Ehrlich and Lazarus, the position of these writers is remarkably clear and their logic appears sound. It is possible that in cases such as the one detailed by Kelly an intercurrent syphilitic infection produced the anomalous conditions found in the blood-making organs. Cases of lymphadenoid degeneration of the bone marrow are perplexing; but there is no reason why this should not be a secondary manifestation as well as that secondary deposits of lymphoid tissue should be found in an organ like the liver. Neither does it seem absolutely essential that the lymph nodes shall be enlarged in order that the lymphocytes shall be swept in abnormal proportions into the blood stream.

Medical News.

ARKANSAS.

Hot Springs Visitors' Protective Association.—At the meeting, October 27, the association endorsed the work done by th executive committee and unanimously chose the same committee to carry on the fight. The committee consists of Drs. Algernon S. Garnett, Thomas E. Holland,, Gaston A. Hebert, Paul T. Vaughan and Howard P. Collings. Dr. Oliver H. Barton was elected president and Dr. Frank W. Jelks secretary of the association.

The Grand Jury Indictment.—Drs. C. Travis Drennen and Thomas E. Holland, Hot Springs, were recently indicted by the grand jury for "drumming." That the act of the grand jury does not meet the approval of the profession is apparent from the following resolution passed by the Visitors' Protective Association:

WHEREAS, It has been brought to the knowledge of the Visitors' Protective Association that the grand jury has found true bills against Drs. C. T. Drennen and T. E. Holland, charging them with soliciting or drumming for patronage or patients; and

WHEREAS, We believe that such result was achieved through the unreliable evidence of one unworthy of credence, an enemy to good government, a violator of the law against drumming, and a personal enemy of the aforesaid physicians and the cause they have in the past espoused and are now so vigorously and ably prosecuting; and

WHEREAS, We believe that the effort of said party to procure said indictment, aided and abetted by others, who are alike strangers to the truth, opposed to good government and the enforcement of the law against doctor drumming, was made because of personal ill will to said physicians and to discredit the organized body of ethical physicians who are making a crusade against the methods of procuring patients by unethical and unprofessional doctors in the city of Hot Springs; now, therefore, be it

Resolved, That it is the unanimous belief of the association that the charges against Drs. Holland and Drennen are false and wholly without foundation; that we hereby express our full confidence in their fidelity to the cause they have espoused; in them personally, as men eminent in our profession, and possessing to the fullest degree that sense of professional ethics which characterizes every reputable physician and gentleman; be it further

Resolved, That, in order to show our full confidence in and esteem for said physicians and to emphasize the assertion that we believe said indictments were "conceived in sin and born in iniquity," we hereby request our attorney, Reid Gantt, Esq., to represent said physicians in their defense if they should need any attorney.

ILLINOIS.

Scarlet Fever.—The school at Sharpsburg has been closed on account of scarlet fever.——Springfield has 30 cases and an epidemic is feared.

Accused Guards Out on Bail.—The two guards at the Illinois Hospital for the Incurable Insane, Bartonville, accused of having caused the death of Thomas Hartley, a patient, have been released on bonds of $10,000 each.

Smallpox.—The disease is said to be raging at New Athens, where churches and schools are reported to be closed.——Bloomington is reported to have 25 cases, and Charleston many cases, while in Westfield quarantine and vaccination has reduced the number of cases to 11.

Chicago.

Council Passes Toy-Pistol Ordinance.—On November 9 the city council passed the ordinance prohibiting the sale, loan or furnishing of toy pistols, guns, etc., to minors, and fixing a $100 fine for each offense.

Death-Causes of the Week.—Pneumonia leads with 67; then follow Bright's disease with 41, heart diseases with 40, consumption and violence with 37, and acute intestinal diseases with 31. The total deaths were 476, equivalent to an annual rate of 13.16 per 1,000.

Demands Muzzling of Dogs.—The Chicago Medical Society, October 28, indorsed the ordinance now before the council requiring the muzzling of dogs during the entire year. A committee will be appointed to attend the council and urge the passage of the ordinance.

Personal.—Dr. Frank Billings had so far recovered as to be able to be removed from the hospital to his residence November 11.——Dr. Sarah Hackett Stevenson is still in St. Joseph's Hospital, and her condition has changed little either for better or worse.——Dr. and Mrs. C. M. Briggs celebrated their golden wedding October 25.——Dr. and Mrs. J. Lewis Stettauer have returned after two years' residence in Europe.

The Prevention of Pneumonia.—The weekly Bulletin of the Health Department announces for the week ended November 7, 67 deaths from pneumonia, 14 per cent. of the total deaths, and 81 per cent. in excess of the deaths from consumption. The report says:

It is clearly the duty of the sanitarian and the worker in the field of preventive medicine to do what in him lies toward education in the precepts of healthful living. A simpler housing, with abundant facilities for the access of sunshine and fresh air, and space enough for each individual; a simpler raiment, which shall preserve the natural power of the skin to resist the effects of draughts and chills and "colds"; a simpler dietary, which shall not overtax the digestive system, and less cookery so that the teeth may have sufficient exercise to prevent their premature decay; more exercise in the open air and, in general, a resort to the simpler and more natural modes of life to which each and every one of us was born, and out of which each and every one of us is removed as promptly as civilization can act.

Pure Milk Saves Babies.—Over 190,000 bottles of sterilized milk were distributed as the first season's work of the milk commission of the Children's Hospital Society. From 31 substations supplies have been distributed daily to thousands of poor people all over Chicago. At the social settlements, dispensaries and hospitals the following poster has been displayed:

Fifty per cent. of children die when less than 5 years old, principally because of improper feeding. Pure pasteurized milk for babies of all ages and conditions sold at cost.

Health Commissioner Reynolds' opinion of the value of the work is indicated by the following letter addressed to Mrs. George M. Moulton, chairman of the distributing committee:

I am greatly pleased at the opportunity afforded me—by your request for the mortality figures of children under 5 years of age during the summer of 1903—to express my appreciation of the commission's work.

During the season there were 2,385 deaths of this age, or 12.6 per 10,000 of the total population. In the summer of 1902 the proportion of such deaths was 13.3, and in that of 1901 was 14.3 per 10,000.

The reduction this year is especially significant in view of what was expected as a result of the single daily delivery of milk. Children's physicians and sanitarians were apprehensive of a murderous increase of child mortality through the feeding of milk from 48 to 60 hours old before it reached the young.

Fortunately this apprehension was not realized, chiefly, as I am convinced, through the 190,000 bottles of sterilized milk distributed through your commission.

The community, and especially mothers in the congested districts, owe you and your colleagues a debt of gratitude.

MARYLAND.

Typhoid at Insane Hospital.—There are five cases of typhoid fever at Springfield Hospital for the Insane at Sykesville. Dr. Clark thinks it was introduced by an attendant as the water supply is above suspicion.

Baltimore.

Lectures on History of Medicine.—The course on the history of medicine at the University of Maryland began on October 28 and will continue during the session on the second and fourth Wednesdays of the month.

Public Baths a Success.—Public bathhouse No. 3 will be begun shortly. There were 1,800 more persons using the baths in October, 1903, than in October, 1902. Mr. Henry Walters has given $93,000 for the baths.

Changes at Woman's College.—At the Woman's Medical College the following changes are announced: Dr. H. Warren Buckler has been appointed professor of practice of medicine

and therapeutics, Dr. Henry Lee Smith professor of medicine, and Dr. J. H. Mason Knox professor of diseases of children.

Antitoxin Lowers Diphtheria Mortality.—Dr. W. Royal Stokes, city bacteriologist, in a recent address, said that since the introduction of the public distribution of diphtheria antitoxin, the rate of mortality from this disease in Baltimore has fallen from 50 per cent. in 1894 to 13 per cent. at the present time.

Vital Statistics.—There were 148 deaths last week, a proportion per 1,000 of 13.95, and for the whites alone of only 12.57. Typhoid fever caused three deaths. During October 776 deaths and 731 births were reported. There was 1 death from smallpox. Typhoid fever was much less prevalent than in 1902.

Suing and Sued.—Dr. George A. Strauss has sued the United Railways and Electric Company for $10,000 damages for fracture of an arm and ribs received in the premature starting of a car.——Drs. John W. Chambers and Thomas S. Latimer have been sued for $25,000 damages by a woman who was operated on at the City Hospital.

Personal.—Dr. Charlotte Murdoch has been made superintendent of the Deaconesses' Home recently established by the Presbyterian Church in Baltimore.——Dr. Ernest C. Leonard has been made lecturer on materia medica at Maryland Medical College.——Dr. A. K. Hadel has been elected president of the Society of the War of 1812.——Dr. John T. O'Mara, resident physician of St. Agnes' Sanitarium, sailed for Vienna, November 5.

MASSACHUSETTS.

Cornerstone Laid.—The cornerstone for the new Deaconess Hospital, Longwood, Boston, was laid with appropriate ceremonies, November 5.

Poisoned by Belladonna.—On the night of October 27 eleven patients in the State Hospital at Tewksbury were in some unknown way poisoned by belladonna. There were no serious results and the accident is being investigated by the superintendent.

Music for Hospital Patients.—During November a company of musicians under the direction of Dr. John Dixwell is giving concerts at the hospitals of Cambridge and Somerville, the Massachusetts General Hospital and the Insane Hospital at Forest Hills.

Nursing Taught in Public School.—For the first time in the public schools of America nursing is one of the subjects taught. The school is the Evening High School in Charlestown, and the teacher, Dr. Laura A. C. Hughes, is president of the Boston Society of the Red Cross Association.

Tufts Medical School News.—Tufts Medical School begins the year with 412 students, an increase of 23 over last year. ——Dr. Harold Williams, dean and professor of theory and practice, has a leave of absence for 10 months. His lectures will be given by Dr. Robert W. Hastings.

Typhoid in Springfield.—Typhoid fever has been somewhat prevalent in Springfield, especially in that portion of the city known as the "McKnight District." The source was traced to an infected spring from which many children drank. The disease has hence affected more than ordinarily the children of the well-to-do families in this residence district.

For New Floating Hospital.—Earnest efforts are being made to secure funds for the construction of a new Boston Floating Hospital. The old boat is too small, and will require a large outlay to make her safe for another season. More than $12,000 has already been subscribed. The annual meeting of the hospital corporation on November 2 resulted in the reelection of the old officers.

Death and Disease.—For the four weeks ended November 7 there were 724 deaths in Boston, a decrease from last year's record of 162. There were reported to the board of health, 262 cases of diphtheria, with 20 deaths; 91 of scarlet fever, with 4 deaths; 91 of typhoid fever, with 15 deaths; 246 of measles, with 5 deaths; 137 of tuberculosis, with 71 deaths; 61 deaths were reported from pneumonia, 3 from whooping cough, 67 from heart disease, 16 from bronchitis and 21 from marasmus, and one case of smallpox, imported from Bangor, Maine. The latter is the first case of the disease to occur in the city since last spring.

MICHIGAN.

Conference of Health Officers.—The State Board of Health has decided to hold the annual conference of health officials at Ann Arbor, Jan. 7 and 8, 1904.

Board Elects Officers.—The State Board of Medical Registration has reorganized by the election of Dr. James H. Cowell, Saginaw, as president, and Dr. Beverly D. Harison, Sault Ste. Marie, as secretary.

Sentence Deferred.—In the case of Dr. William W. Phippen, Grand Rapids, who pleaded guilty to the technical charge of practicing medicine without a license, the judge deferred sentence until January to give the defendant time to present proofs that the refusal of the State Board of Registration in Medicine to issue him a license was based on a misapprehension.

Outbreaks of Communicable Diseases for the Quarter.—The secretary has presented to the State Board of Health his report of work done in the office during the quarter ending September 30, 1903. This report includes a statement of the number of outbreaks of dangerous communicable diseases, reported and acted on during the quarter, as follows: Diphtheria, 95; measles, 99; whooping cough, 100; smallpox, 104; meningitis, 116; scarlet fever, 151; typhoid fever, 266; consumption, 369; total for the eight diseases, 1,300 outbreaks. Compared with the average in corresponding quarters in the ten years, 1893-1902, the reports from regular observers indicate that in the third quarter of 1903 diphtheria, pleuritis, scarlet fever and smallpox were more than usually prevalent, and meningitis, cholera infantum, cholera morbus, consumption, dysentery, erysipelas, intermittent fever and remittent fever were less than usually prevalent.

Diseases Which Householders Are Required to Report.—The State Board of Health has prepared a circular in which it is declared that consumption, pneumonia, cerebrospinal meningitis, typhoid fever, diphtheria, whooping cough, measles, scarlet fever, smallpox, glanders, and rabies are dangerous communicable diseases, and therefore "diseases dangerous to the public health," required by law to be reported. Every case of each of these diseases must be reported to the local health officer by the householder, hotel keeper, boarding-house keeper or physician. The law is then quoted showing the duty of such persons to so report. The use to be made of such reports is not the same for all diseases, because the manner of spreading and the measures for the restriction are not the same for all diseases. Houses infected with some diseases are to be placarded, with others not. Persons having some of the diseases are to be isolated. Relative to each of those diseases, such facts are published by the State Board of Health, and a pamphlet on any one of these diseases, or on all of them, will be sent to any person interested, who requests it from the office of the board at Lansing.

MISSISSIPPI.

Personal.—Dr. L. B. Neil, Raymond, has been appointed third assistant physician of the State Insane Hospital, Jackson.

Wants Bureau of Vital Statistics.—Dr. Harris A. Gant, Jackson, president of the State Board of Health, will appeal to the legislature to establish a bureau of vital and mortuary statistics, and also a state bacteriologic laboratory.

Unlicensed Practitioners.—The State Board of Health will hereafter publish the names of unsuccessful applicants in examinations for license to practice. These have heretofore been withheld because of consideration for the feelings of the unsuccessful applicants. The board has found that some of these have entered into practice in defiance of the board and will, therefore, make public the names.

NEBRASKA.

Insane from Drugs and Liquor.—Dr. James C. Dwyer, Valentine, has been adjudged insane and ordered to be committed to the State Insane Hospital. His condition is said to be due to intoxicating liquor and drugs.

Personal.—Dr. John C. F. Bush, Wahoo, has returned from Europe.——Dr. Andrew Johnson, Beatrice, has moved to Wahoo.——Drs. J. F. B. Kalol and Nicholas F. Steiner, Omaha, sailed for Europe, October 17.——Dr. Henry L. Akin, Du Bois, has gone to Vienna.

Society Meets.—The fourth quarterly meeting of the Saunders County Medical Society was recently held at Wahoo. Drs. W. J. Pinkerton, Mead, and J. M. Willis, Colon, read papers, and Drs. Andrew Johnson, Wahoo, J. G. Smith, Weston, and Charles W. Hickey, Ithaca, were admitted to membership.

NEW JERSEY.

Hospital Benefit.—The benefit festival recently held to aid the German Hospital Society of Newark netted $2,188.84 to the hospital fund.

Physician Fined.—In the case of Dr. Robert C. Ribbans, Newark, charged with having failed to report a case of smallpox, the court gave judgment for $50, and the defendant gave notice of appeal.

Orthopedic Dispensary.—A free public orthopedic dispensary has been established in the Orange Valley section of Orange, by charitably disposed citizens. The work will be under the personal direction of Dr. Russel A. Hibbs, New York City, assisted by Dr. Henry A. Pulsford, South Orange.

Threatens Suit.—An Italian lawyer of Newark, whose name was by mistake included in a list of illegal advertisers of medicines, and who was, consequently, reported by the State Board of Medical Examiners as practicing without a license, has declared that a libel suit against the board will be necessary to set him right with his countrymen.

NEW YORK.

Prosecuted by Medical Society.—On the complaint of the Saratoga County Medical Society, Jeremiah Richards of Waterford was arrested, October 21, charged with practicing medicine without a license. He waived examination.

To Investigate Summer Resorts.—Dr. Daniel Lewis, state commissioner of health, will ask the legislature for an appropriation of $10.000 to establish a new bureau in the department, to be known as the Bureau of Water Inspection and Drainage, with especial reference to summer resorts.

The D. W. Harrington Lectureship.—The medical faculty of the University of Buffalo has chosen Dr. Samuel J. Meltzer, New York, to deliver these lectures for 1903. The subject selected by Dr. Meltzer is "Edema, a Consideration of the Physiological and Pathological Factors Concerned in Its Formation." The lectures will be delivered in the medical college, November 30, and December 1, 2 and 3, at 5 p. m. Members of the medical profession are cordially invited to attend.

New York City.

Wanted for Medical Building.—In the "want list" of $3,250,000 in the annual report of the chancellor of the New York University, an item of $750,000 appears for medical college buildings.

Gypsy Illegal Practitioner.—Lottie Karl, a fortune teller and clairvoyant, was convicted, November 7, of practicing medicine without a license, and was sentenced to pay a find of $150 or to be imprisoned 60 days in the city prison. The complaint was made at the instance of the New York County Medical Association.

Endorses Health Commissioner.—A testimonial signed by 35 representative physicians of New York City has been sent to the daily press, expressing the great appreciation of the physicians of the city of the work accomplished by Health Commissioner Ernst J. Lederle and his advisory board in the last two years, and offering their public acknowledgments.

Control of Tuberculosis.—Dr. Hermann M. Biggs delivered a lecture at Columbia University, November 6, on "The Administrative Control of Tuberculosis." He declared that 60 per cent. of the deaths in New York were caused by tuberculosis, and that the mortality from this cause was especially great among tenement children at the age of four or five years.

Pavilion for St. Luke's Hospital.—Mrs. Margaret J. Plant has offered to build for the hospital a new pavilion in which private patients may have modern and even luxurious accommodations and service. It is purposed to provide accommodations for more than one hundred patients, so that, if desired, a patient may have a suite of rooms and may be attended by relatives or friends.

PENNSYLVANIA.

Verdict for Physician.—In the suit of Albert E. Foltz, Edison, for damages for alleged malpractice, against Dr. Allison A. Stamm of Mohnsville, the jury brought in a verdict for the defendant.

Smallpox.—Sharon has about 30 cases.——On November 2 four deaths occurred in Pittsburg, and four new cases were discovered.——Allegheny on the same day had 37 cases under treatment, 21 in the isolation hospital and 16 under quarantine.

Hospitals Completed.—The northern wing of the new Lancaster General Hospital has been completed, and is ready for occupancy.——Uniontown Hospital, erected at a cost of $75,000, has been completed, accepted by the directors, and will soon be ready to receive patients.——Susquehanna City Hospital was formally opened October 10.

Land and Money to Hospitals.—By a decree of the Orphans' Court, the legacy of $20,000 bequeathed by the late C. L. Magee, Pittsburg, to the late George M. von Bonnhorst, reverts to the Elizabeth Steel Magee Hospital fund.——Misses Alice and Mary Mossop have presented to Clearfield Hospital four acres of land and $20,000 in cash, for the building of a model hospital as a memorial to Fred G. Mossop, a deceased brother, who was a director of Clearfield Hospital.

Personal.—Dr. John C. Calhoun, Allegheny, in charge of the isolation hospital, has resigned, and Dr. William H. Gardner has been appointed in his stead.——Dr. Daniel W. Jeffries, Chester, has been appointed state censor by the Delaware County Medical Society.——Dr. Horace F. Taylor, Chester, was seriously cut and burned by a bottle of carbolic acid breaking in his hands.——Dr. Frank C. Knowles, Philadelphia, is taking a three months' tour of Europe and Asia.

Chester Hospital Staff Organized.—At the annual meeting of the staff, October 20, Dr. J. L. Forwood was re-elected chief of the surgical staff and Dr. D. M. McMasters chief of the medical staff. Dr. F. Farwell Long was assigned as lecturer on special surgery; Dr. Ellen E. Brown, on obstetrics; Dr. J. L. Forwood, on general surgery; Dr. Katherine W. Ulrich, on diseases of children; Dr. F. Otis Bryant, on anatomy; Dr. Samuel R. Crothers, on emergencies; Dr. D. M. McMasters, on general medicine; Dr. Edward W. Bing, on materia medica; Dr. L. Haines Crothers, on hygiene, and Dr. Leon Gottschalk, on physiology.

Philadelphia.

Reception for Weir Mitchell.—The Medical Club of Philadelphia will tender a reception to Dr. S. Weir Mitchell at the Hotel Bellevue, November 20.

Dr. Filbert's Will.—By the will of the late Dr. Ludwig S. Filbert, the estate, which is appraised at $300,000 or more, after the payment of a few small legacies, is divided equally between his wife, son and daughter.

Finsen Light Laboratory.—A specially constructed laboratory for *x*-ray and Finsen light research is being erected in connection with the University Hospital. At the last session of the legislature $25,000 was appropriated for this purpose. Dr. Henry K. Pancoast will be in charge of the new department.

Personal.—Dr. James E. McCoy has been appointed physician to the medical dispensary of the Children's Hospital.—Dr. B. Franklin Stahl has been appointed medical director of St. Agnes' Hospital, vice Dr. William H. Parish, deceased.——Dr. Leo Loeb has been appointed assistant demonstrator in pathology at the University of Pennsylvania.——Dr. Howard S. Anders has been made assistant professor of physical diagnosis in the Medico-Chirurgical College.

Smallpox Regulations.—The board of health recently passed a resolution directing all inmates of houses where smallpox develops to be removed to the Municipal Hospital for antiseptic baths and disinfection of clothing. The resolution provides for such disinfection in case of scarlet fever and diphtheria when the medical inspector deems it necessary. The action is especially to protect Director Martin from legal complications in carrying out such measures, as he has been several times threatened with suit for damages.

GENERAL.

The Army Medical School began its seventh annual session, November 3, with twenty-seven student officers in attendance. The faculty consists of the following officers: Col. Chas. Heizmann, president of faculty and professor of military medicine; Major William H. Arthur, professor of duties of medical officers in peace and war; Major William C. Borden, professor of military surgery; Major Walter D. McCaw, professor of military hygiene and lecturer on tropical diseases; Major James D. Glennan, ophthalmology and optometry; Captain F. P. Reynolds, instructor in hospital corps drill and medical department administration; Captain C. R. Darnall, secretary of faculty, instructor in sanitary chemistry and operative surgery; Lieutenant James Carroll, professor of bacteriology and clinical microscopy, and Captain H. G. Trout, instructor in equitation.

The Yellow Fever Scourge.—Thousands of cases of yellow fever in Mexico and hundreds in Texas are reported by the representative of the U. S. Public Health and Marine-Hospital Service. The death rate is about 5 per cent. A total of 748 cases and 74 deaths is reported at Laredo, Tex., up to November 9. Railroad schedules are interrupted and trains avoid infected towns or run through rapidly with car doors and

windows closed or else suspend passenger trains. Thus there is also scarcity of provisions in some places. The Little Rock (Ark.) Board of Health established a quarantine against San Antonio, Laredo and other infected points. Forepaugh's circus was also enjoined from stopping in Little Rock en route north from Texas. Other cities have quarantined against Texas cities. El Paso, however, has thrown wide open her gates and will receive yellow fever refugees or sufferers without restriction. This action was taken on the ground that the mosquito concerned in the propagation of yellow fever can not exist above 1,200 feet, especially in a dry climate. El Paso's elevation is 4,000 feet, and her air dry. It was, therefore, decided by the authorities of that city that no danger of the transmission of the disease exists there.

CANADA.

Smallpox in New Brunswick.—Fourteen cases of smallpox are reported in Madawasha County, N. B., on the border of the State of Maine.

Typhoid Fever in Manitoba.—This disease has been very prevalent this autumn in Manitoba and Winnipeg. In Winnipeg one of the Industrial Exhibition buildings has been converted into a hospital for 35 patients, with a house surgeon and a staff of nurses in charge.

Toronto's Health Statistics.—During October, 1903, there were 118 cases of diphtheria, 23 of scarlet fever and 18 of typhoid fever. The deaths from contagious diseases in Toronto during September and October were: Scarlet fever, one in each month; diphtheria, in September, 7; in October, 13; typhoid, 3 and 6; consumption, 28 and 19.

Druggists and Physicians Charged with Violations of Laws.—The Pharmaceutical Association of Quebec has laid charges in the police court against a number of Quebec physicians, accusing them of giving prescriptions to be filled by unlicensed druggists or unregistered drug clerks and also against several druggists for selling poisons to the public contrary to the provisions of the pharmacy act, and for permitting unqualified clerks to fill prescriptions.

Ontario Birth Rate.—The provincial board reports 47,796 births during 1902 in Ontario, as compared with 46,061 in 1901, or an increase of 1,735. The number of marriages in 1902 was 18,072, an increase of 37 over 1901. Deaths during 1902 numbered 27,864; in 1901 29,608, showing the substantial decrease of 1,744. Dr. Bryce, secretary of the provincial board, attributes the increased birth rate to the crusade instituted by the press of the country and by the ministers of all denominations against race suicide.

Manitoba Medical College Opens.—This college began its twenty-first consecutive session September 21 with the largest attendance in its history. There are over forty in the freshman class. The most particular feature of the Manitoba medical act is that there is no council examination for the graduates of the Manitoba University. All graduates of this university are licensed to practice on payment of the registration fee of $75. The following changes in the staff have been made since last session: Dr. J. O. Todd has been elected to the chair of anatomy in succession to the late Dr. Neilson. Dr. James McKenty and Dr. James Pullar have been appointed assistant demonstrators in anatomy. Dr. W. L. Watt will conduct the practical and physiologic chemistry, and Mr. J. S. Pierce will teach the organic and inorganic chemistry.

Five-Year Medical Course in Quebec.—The Quebec Board of Physicians and Surgeons at a recent meeting decided to lengthen the medical course from four to five years. Another important item was the repealing of that section of the by-laws of the Quebec council which permitted men having British licenses to register and practice in the province of Quebec without having to undergo any further examination. A third question debated was the compulsory B. A. course, or "cours classique complet," before admission to the study of medicine n that province. The law in relation to this was so amended that the Catholic or French speaking candidate would have to pass such examination, but no change was made for the Protestant or English speaking candidate. These changes will be reported to the Quebec legislature, and the probability is that they will become law without alteration.

FOREIGN.

Plague at Rio de Janeiro is reported to the extent of 29 deaths and 52 new cases and 109 cases under treatment during the week ended November 5.

King Edward Sanatorium.—The cornerstone of the King Edward VII Consumption Sanatorium was laid November 3 at Midhurst, Sussex, Eng., by the king. One million dollars was given for this by Sir Ernest Cassel.

Another Case of Lethargic Sleep.—A young man in the province of Warsaw sank into a lethargic slumber last April and it has been impossible to arouse him. He wakens sufficiently to take a little liquid food every three weeks, and then succumbs at once to sleep.

International Congress of Applied Chemistry.—The committee in charge of the sixth congress, to be held at Rome in 1906, is already diligently at work. Professor Paterno was appointed president and the executive committee consists of Professors Piretti, Nasini, Ciamician and Menozzi.

Plan for Serum Institute in Germany.—The German authorities have about decided to found a serum institute for the nearly gratuitous distribution of antitoxins and serums for various diseases, and for research thereon. It is to be modeled on the lines of the Paris Pasteur Institute and will be called the Behring Institute.

Continental Anglo-American Medical Society.—The object of this association is purely social. The members are located mostly in the various European watering-places or in the large cities, and gather once a year for social intercourse. The fifteenth annual dinner was held at Paris, October 9, with thirty members in attendance.

Driven to Suicide by a Charlatan's Publications.—A comparatively young man committed suicide last month in Vienna. He left a farewell letter to his wife and children in which he stated that he had been driven to suicide by the knowledge that the affection from which he was a sufferer entailed insanity in time, adding "See Bilz's book."

The Operation on Emperor William.—The Emperor of Germany had removed from his larynx, November 7, a small pea-sized growth, which, according to the newspaper reports, was probably a simple papilloma. The operation was very simple and brief, and the growth is declared by the physicians in charge to have no suggestion of malignancy.

Italian Congress of Pathology.—This congress was held at Florence in October and appointed Milan as the place for the next meeting, which will be held during the spring of 1905. Professors Golgi and Foa were appointed a committee to confer with the German Pathologic Society in regard to whether the approaching congress could not be made international.

Subsidies for Authors.—The well-known "Military Medical Academy" at St. Petersburg appropriates annually nearly $800 as a fund for professors in the academy who during the year have published text-books on their special branches of science. This year it was divided between Bechtereff and Kravkoff, as each had published a manual, the former on the functions of the brain, and the latter on pharmacology.

Medical Affairs in Constantinople.—A new medical school has been constructed at Constantinople, said to be a model. Prof. R. Rieder of Bonn has been in charge of the work, and the new building was to have been dedicated November 6. The sultan became convinced that the radical political element might find a footing in the new school, and he has consequently ordered the project to be abandoned. Professor Rieder returns to Bonn and the building stands vacant.

Antituberculosis Dispensary in Berlin.—Von Leyden announces that a dispensary is soon to be opened at Berlin, modeled on those in France and Belgium, for tuberculous outpatients alone. At first it is to be restricted to persons dismissed from the great Belzig sanatorium. They are to be kept track of and their environment made as favorable as possible, with supervision as to whether they continue to conform to the prophylactic measures recommended.

Heavy Fine for Failure to Find Symptoms.—A Spanish physician recently testified that he could detect nothing abnormal in a man who had apparently recovered complete health after a blow on the head. The injury had at first produced symptoms of slight concussion of the brain, but these had all subsided at the time of the medical examination. A few days later other physicians noticed the presence of symptoms of cerebral concussion and the first expert was fined by the court $300 for false testimony. The *Siglo Médico* publishes a vigorous protest against this decision "which opens a new horizon of misfortune for the already sufficiently unfortunate medical class."

Progress in Peru.—Two members of the profession have been successively minister of the interior in Peru during the last year, Drs. D. Matto and M. C. Barrios. The former organized three maritime disinfecting stations at Paita, Callao and

llo. Dr. Barrios assumed office last September, and within a week he had secured the passage of a law by the senate, organizing a national board of public health as a section of his department. Its duties are to be similar to those of our marine-hospital service, with a director and a subdirector for the subsections of hygiene and demography. Peru, with nearly 1,000,000 square miles, has only 4,000,000 inhabitants, and the population has been declining or stationary for several years.

Campaign Against Charlatans and Proprietary Medicines in Germany.—The Cologne courts recently fined a "magnetopath" named Offermann $250 for his pretensions that he was able to cure all diseases. The same court (Landgericht) has also recently sent out a notice warning the public against "Warner's Safe Cure," which is being advertised extensively throughout the country. The notice enumerates the ingredients of the remedy and reiterates that there is no such thing as a universal medicine to cure all diseases, and that the price of the remedy in question far exceeds the actual value of the ingredients. The public is therefore warned against purchasing this useless preparation (nutzloses Mittel). The local board of health at Carlsruhe has issued a similar notice in regard to "Flucol," a much advertised oil remedy for pains of all kinds, asthma, rheumatism, etc., warning against its internal use on account of the danger of injury to the kidneys from its ingredients.

Professional Secrecy.—The national board of health at Buenos Ayres was recently consulted by the courts in regard to a suit brought by a physician against an estate for services rendered. The physician, in bringing the suit, enumerated the particulars of his services and demanded remuneration for conducting a premature delivery, curetting and after-care. The patient was an unmarried woman, and the affair had been conducted at her request with complete secrecy. The board of health materially reduced the amount to be paid, and severely censured the physician for his lack of professional secrecy in the matter. The death of the patient in the interim was no excuse for proclaiming the details of the services rendered. They also censured him for conducting such an operation without insisting on the presence of another medical man. The action of the board was modeled on Brouardel's maxims, which it cites from his work, "La Responsabilité Médicale." Several pages are devoted to the case in the *Semana Médica* of September 17.

Recent Important Medical Congresses in Europe.—In Germany the Congress of Physicians and Naturalists was held at Cassel, September 20 to 26. This is the annual meeting of the association devoted to research and practice in the medical and allied sciences. The attendance is always well into the thousands. The principal feature this year was Behring's address on tuberculosis, which was reviewed on page 994. In France the congresses of surgery and urology have just concluded their sessions at Paris. The subjects discussed at the former were "Exclusion of the Intestine," with addresses by H. Hartmann of Paris and others, and "Brain Tumors." The subjects appointed for discussion at the Congress of Surgery next year are "Hematology from the Surgical Standpoint," with an address by Tuffier of Paris, and "Surgical Treatment of Biliary Cirrhosis," with address by Monprofit of Angers. The Congress of Urology discussed "Rebellious Cystitis" and "Surgery of the Genito-urinary Organs," with addresses by Imbert of Montpellier, Pasteau of Paris, and others, Professor Guyon in the chair. Among the communications presented on surgery of the genital organs and urethra was one by Dr. Cumston of Boston. Our French and German exchanges give full particulars of these congresses in their last and current issues.

Correspondence.

A National Research Laboratory.

MILTON, KY., Oct. 28, 1903.

To the Editor:—Your endorsement of the Smallpox Research Laboratory in Cleveland (THE JOURNAL, Oct. 24, 1903, p. 1029) is commendable and justified. Would it not be better to have a national laboratory, under the auspices of a department of health, for studies on the etiology and pathology of all contagious and infectious diseases? Does not this work in Cleveland and Boston emphasize the need of the strong arm of the government to prosecute this important work?

S. E. HAMPTON, M.D.

[Researches are now being carried on in the Hygienic Laboratory of the Public Health and Marine-Hospital Service on the etiology and pathology of smallpox and of other diseases. A building, thoroughly equipped, has recently been completed, and is now being used for the purpose. The Army Medical Department is also doing good work of this kind in connection with the Army Medical School. The lamented Walter Reed, at the time of his death, was engaged in some interesting work on smallpox. The laboratory connected with the Medical Department of the Army in Manila is doing good work in the investigation of tropical diseases.—ED.]

Dosage of Carbolic Acid.

NEW ORLEANS, LA., Nov. 2, 1903.

To the Editor:—In an editorial in THE JOURNAL, October 31, you express surprise at the possibility of administering carbolic acid in more than 7-drop doses without grave results. I, too, had been taught to regard the internal administration of carbolic acid as a dangerous procedure until I became a surgeon in the British African service in 1893, where I learned that 15-drop doses often repeated afforded the best cure for the diarrhea and dysentery so prevalent and fatal along the west coast of Africa. W. LAURENCE STEVENSON, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

MEDICAL PRACTICE IN SWITZERLAND.

GUALALA, CAL., Oct. 29, 1903.

To the Editor:—Will you kindly inform me, under Queries and Minor Notes in THE JOURNAL: 1. If foreigners can take up medical practice in Switzerland? 2. The names of the medical journals in Switzerland and where they are published? ENQUIRER.

ANS.—1. Foreigners must pass through some of the government examinations—the first, third and fourth—which are conducted in German and French and which are likely, we believe, to be rather thorough. One will probably also have to show a longer period of study of medicine than is demanded in this country. 2. At least three medical journals are published in Switzerland, possibly more: The *Correspondenzblatt für die Schweizerische Aerzte*, the *Revue Medicale de la Suisse Romande* and the *Bull. Internationale de la Soc. de la Croix Rouge*. The first is published in Basle, the other two in Geneva.

SADISM.

DETROIT, Nov. 4, 1903.

To the Editor:—In THE JOURNAL, October 31, p. 1098, under "A Warning to Wealthy Parents," there occurs the phrase "proved to be a typical case of extreme sadism." The last word is a new one to me; neither the Standard nor Century dictionaries have it. Can you give its true meaning and derivation? There may be others who do not like to pass over words that are new to their vocabulary.

G. C.

ANS.—The word means a sexual perversion which obtains satisfaction in inflicting cruelty on others. It is derived from the Marquis de Sade, a historical example of this type, and himself an author of works on sexual matters published in the latter part of the eighteenth century.

Marriages.

CHARLES H. AYLING, M.D., Gridley, Ill., October 28.

OLIVER P. COE, M.D., to Miss Kathryn Hunter, both of Cincinnati, November 11.

CLARK A. BUSWELL, M.D., Chicago, to Miss Emma Rink of Elgin, Ill., November 4.

EMORY M. GOODWIN, M.D., to Miss Edith Shumway, both of Glenville, Ohio, October 27.

BENJAMIN D. MOSHER, M.D., to Miss Minnie Hess, both of Troy Grove, Ill., October 23.

ELMA L. JANES, M.D., Madison, Wis., to George H. Townsend of Dayton, Ohio, October 29.

LOUIS V. SAPH, M.D., San Jose, Cal., to Miss Nancy Wallace of Woodland, Cal., October 21.

JAMES V. MAY, M.D., to Miss Viola Florence Pickett, both of Wautoma, Wis., October 29.

ENOCH SAMUEL COOPER, M.D., Peachtree, Ala., to Miss Louise Rosine Krudop of Mobile, October 28.

J. ROYSTON GREEN, M.D., Baltimore, to Miss Mary Chew Grason, at Towson, Md., October 28.

ROBERT JAMES CHRISTIE, JR., M.D., to Miss Edith Eliza Turner, both of Quincy, Ill., October 26.

RICHARD LAWRENCE CAMPBELL, M.D., East St. Louis, Ill., to Miss Leva A. Crane of Pekin, Ill., October 29.

T. JACOB SMITH, M.D., Princess Anne, Md., to Miss Sophonisba P. Handy, at Schoharie, N. Y., October 27.

ORVILLE WARD WILSON, M.D., Clearfield, Pa., to Miss Lottie Idella McCloskey, of Lock Haven, Pa., October 29.

ANDREW A. BRADFORD, M.D., Cambridge, Ohio, to Miss Alice E. Elder of Bremen, Ohio, at Columbus, October 22.

JESSE W. INGRAM, M.D., Whatcom, Wash., to Miss Anna Grace Newmyer of Spokane, Wash., at Walla Walla, Wash., October 23.

Deaths.

Julian J. Chisolm, M.D. Medical College of the State of South Carolina, Charleston, 1850, died at Petersburg, Va., November 2, aged 73. After studying abroad he began practice in Charleston, and by his early recognized ability rose to the professorship of surgery in 1858. In the Civil War he obtained the first medical appointment and also treated the first wounded in the war (at Fort Sumter). He was the author of a "Manual of Military Surgery," which was the official text-book of the Confederate surgeons. He resumed his chair in 1865, but removed to Baltimore in 1869, and was at once made professor of operative surgery and diseases of the eye and ear in the School of Medicine of the University of Maryland. He was also dean of the faculty from 1869 to 1874. In 1873 he gave up surgery and devoted himself thenceforth exclusively to his specialty, in which he achieved an international reputation. He was a most prolific writer, a skillful operator and a man of extraordinary energy. He was a born teacher. He was chairman of the ophthalmologic section of the International Medical Congress of 1887. The great work of his life was the founding in 1877 of the Presbyterian Eye, Ear and Throat Hospital of Baltimore, one of the largest special hospitals in the country. In 1894, shortly after a trip to Europe, he was stricken with apoplexy and aphasia, and his active work ceased. He then gradually failed until his death.

William Reed McMahan, M.D. Rush Medical College, Chicago, 1868, one of the most prominent practitioners of southern Indiana; a veteran of the Civil War; in 1882, 1883 and 1884 professor of pathology in the Evansville (Ind.) Medical College; for 18 years chief surgeon of the Louisville, Evansville and St. Louis Railway; for two years consulting surgeon of the Lexington and St. Louis division of the southern railway system; a member of the American Medical Association; in 1903 first vice-president of the Southern Railway Surgeons' Association; one of the founders of the Dubois County Medical Association, and a member of the Indiana State Medical Society, died from apoplexy at his home in Huntingsburg, Ind., October 23, aged 60. He was for two years president and for six years a member of the board of control of the Indiana Southern Hospital for the Insane.

Robert Wood Mitchell, M.D. Tulane University, New Orleans, 1856, a member of the American Medical Association, American Public Health Association, Medical Society of the State of Tennessee, Memphis and Shelby County Medical Society and National Board of Health, professor of materia medica in Memphis Medical College, founder of the City Hospital, Memphis, secretary of the local board of health, during the Civil War regimental, brigade and division surgeon in the Confederate service; a pioneer practitioner of Memphis, who performed faithful work in yellow fever epidemics and was made one of the board appointed by congress to investigate the cause of yellow fever, died at his home in Memphis, November 2, from heart disease, after a brief illness, aged 71.

Simon Pollak, M.D. University of Vienna, Austria, 1835, the oldest practitioner of St. Louis; a member of the American Medical Association; one of the founders of the Missouri State School for the Blind, who opened, in 1861, the first eye and ear clinic west of the Mississippi, died at his home in St. Louis, October 31, aged 90. During the Civil War he served on the U. S. Sanitary Commission. He was many times treasurer and once president of the St. Louis Medical Society. Dr. Pollak was one of the quartet of St. Louis veteran physicians in whose honor a banquet was given by the medical profession of the city on April 14 last.

Archibald Atkinson, M.D. University of Pennsylvania, Philadelphia, 1854, afterward a student in Dublin and Paris for two years; brigade surgeon in the Confederate service during the Civil War; professor of materia medica and therapeutics in the College of Physicians and surgeons, Baltimore, and later in the Baltimore Medical College, died at his home in Baltimore, October 29, from Bright's disease, aged 71.

Leon de Chesne, M.D. University of Louvain, Belgium, 1879, a member of the American Medical Association and the Wisconsin State Medical Society, and for thirteen years a prominent practitioner of Sturgeon Bay, Wis., died at Presbyterian Hospital, Chicago, October 28, from carcinoma of the tongue, after an illness of nine months, aged 51.

Lorenzo Traver, M.D. Albany (N. Y.) Medical College, 1857, surgeon U. S. Navy until 1868, and thereafter a resident of Providence, R. I.; a member of the American Medical Association, Rhode Island Medical Association and Providence Medical Association, died at his home in Providence, October 24, aged 69.

Stephen L. Blachly, M.D. Jefferson Medical College, Philadelphia, 1870, for fifty years a practitioner in Washington County, Pa., and for several years president of the county society, died at his home in Wilkinsburg, Pa., October 28, after a long illness, aged 87. He retired from active practice in 1890.

Joseph Billings Morton, M.D. College of Physicians and Surgeons, New York, 1849, the oldest practitioner in New Jersey, who for several years had compiled the weather reports for the Signal Service Bureau of Elizabeth, died at his home in that city, November 2, aged 77.

Wakeman Briarly Munnikhuysen, M.D. University of Pennsylvania, Philadelphia, 1869, a surgeon in the German army during the Franco-Prussian War, died at his home in Belair, Md., October 27, from paralysis, after a partial invalidism of two years, aged 59.

A. D. Binkerd, M.D. Long Island College Hospital, Brooklyn, 1864, formerly assistant surgeon Third Company U. S. Heavy Artillery, died at his home in Miller's Eddy, West Monterey, Pa., October 27, after a short illness from neuralgia of the heart, aged 78.

Bernard A. Daly, M.D. University College of Medicine, Richmond, Va., 1899, died at his home in Newark, N. J., November 2, from septicemia, resulting from a slight wound received during a surgical operation, four weeks before, aged 27.

John B. Weaver, M.D. Michigan College of Medicine, Detroit, 1881, died suddenly in the City Hall, Lansing, Mich., October 31, aged about 50. Death is supposed to have been due to rheumatism of the heart.

Thomas James Davis, M.D. University of Vermont, Burlington, 1885, superintendent of Charity Hospital, formerly McKane Hospital, Savannah, Ga., died at Sheepshead Bay, N. Y., November 5.

Benjamin Elmore Kell, M.D. Bellevue Hospital Medical College, New York, 1890, of Chester, S. C., died, October 30, at the home of his father, Dr. James T. Kell, Ardreys, N. C., after a long illness.

Robert C. Downey, M.D. Starling Medical College, Columbus, 1864, surgeon of the Thirteenth Ohio Volunteer Cavalry in the Civil War, died at his home in Caldwell, Ohio, October 22, aged 69.

Joseph T. Battle, M.D. Medical College of Georgia, Augusta, 1868, died at his home in Highland Park, Montgomery, Ala., October 22, from rheumatism, after an illness of several days.

Patrick Curran, M.D. Rush Medical College, Chicago, 1878, of Chicago, died at Fort Worth, Texas, where he had gone a year ago for the benefit of his health, October 28, aged 75.

Harvey P. Cox, M.D. University of Louisville, Ky., 1876, of Mackville, Ky., died at the Gray Street Infirmary, Louisville, October 29, from cirrhosis of the liver, aged 51.

Albert U. Evarts, M.D. Louisville Medical College, 1871, died at his home in Laporte City, Iowa, November 3, after a short illness, from Bright's disease, aged 60.

Caleb C. Libby, M.D., a member of the state senate, died at his home in East Pittston, Me., October 27, from kidney disease, after a long illness, aged 56.

Silas Edwin Akers, M.D. University College of Medicine, Richmond, Va., 1898, died at his home at Willis, Va., October 22, from typhoid fever, aged 31.

R. R. MacFarlane, M.D. Trinity College, Toronto, of Seattle, Wash., and Dawson, N. W. Territory, was found dead on a train in Montana, October 24.

Louis Ronchi, M.D. Royal Medical College, Rome, Italy, was asphyxiated by gas at his boarding house in New York, November 3.

E. B. Williams, M.D., died at Nome, Alaska, September 11, from heart disease, aged 48.

Deaths Abroad.

Otto J. F. Nasse, M.D., professor of pharmacology and physiologic chemistry at Rostock from 1880 to 1899, died at Freiburg, October 20. He was a prolific writer on his specialty, and besides his contributions to Pflüger's *Archiv* and other periodicals he published works on the physiology of peristalsis and on the striped muscle substance. His successor at Rostock is Prof. Rudolf Kobert, whose name is also well known by his numerous publications.

D. Tibone, M.D., one of the most prominent gynecologists of Italy, died suddenly at Rome, October 7, aged 70. He had been professor of obstetrics and gynecology at Turin for thirty-eight years.

Friedrich Betz, M.D., died at Heilbronn, October 19, aged 84. He founded the medical journal, *Memorabilien*, in 1856, and conducted it until last year, when its suspension was announced.

R. Seccondi, M.D., professor of ophthalmology at Genoa and a prominent member of the Italian senate.

Miscellany.

CLIPPINGS FROM LAY EXCHANGES.

ANTEMORTEM INQUEST.

"Dr. —— of the State Board of Health was in town yesterday, to hold an inquest over ——, who is suffering from smallpox."—*Houtzdale* (Pa.) *Citizen*, Oct. 9, 1900.

NEW INSTRUMENT.

"Dr. —— . . . does not think the sleeping sickness is caused by a microbe, but by a trysanasometer belonging to the same group of parasites which attacks cattle."—*N. Y. Sun*, Nov. 1, 1903.

POSTMORTEM HEMORRHAGE CAUSES DEATH.

In the biennial report of Queen's Hospital, Honolulu, Hawaii, published in the *Honolulu Bulletin* of August 20, death is said to have been due, in one instance, to "postmortem hemorrhage."

INVOLUTION.

"Dr. —— of Chicago may take the work at Grand Avenue Chapel. . . . . Dr. —— is a converted physician, so he says, until a few years ago he practiced in ——."—*Crawfordsville* (Ind.) *Journal*, September 21.

RENAL CHOLELITHIASIS.

"The many Vermillion friends of —— learn with much regret of his serious condition with kidney trouble. He will submit to an operation in Chicago soon for the removal of a gallstone from his kidneys. . . . ."

NASAL DYSMENORRHEA.

"Dr. —— then read the next paper, which was entitled 'A New Treatment for Dysmenorrhea.' The chief treatment of this nasal infection was cocaine . . . .—Memphis (Tenn.) Report of Mississippi Valley Medical Association.

NEW LOCALITY FOR CANCER.

"Prof. ——, an eminent physician and member of the senate, publishes to-day a long article to demonstrate that —— died of a tuberculosis cancer on the right hydrothorax."—*Rutland* (Vt.) *Evening News*, September 11, and other newspapers.

POST HOC, PROPTER HOC?

In a list of companies incorporated, published in the *New York Journal of Commerce*, Sept. 2, 1903, is "The Mutual Medical Company—Objects: furnish medical attendance and subsequently bury the dead; capital $2,000. Incorporators . . ."

AN ORACULAR JURY.

"A coroner's jury in Holly, in its verdict on the death of a suicide, found that 'the oracle of his heart was weak, and he would soon have died of rupture of the oracle if he had not taken his own life."—*Grand Rapids* (Mich.) *Evening Press*, October 3.

MEDICAL STUDENTS CUT THROAT.

"——, who has been deaf and dumb for four years as the result of a mining accident . . . . has been restored to speech and hearing by students of —— Medical College, Chicago, ... who cut ——'s throat open and removed clots of blood and supplied him with artificial eardrums."—*Chicago Tribune*, October 26.

State Boards of Registration.

COMING EXAMINATIONS.

Board of Medical Examiners of the State of California, City Hall, San Francisco, Dec. 1.

New Mexico Board of Health, Santa Fe, Dec. 7.

Examining Board of Medical Society of Delaware, Dover, Dec. 8.

Board of the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, Dec. 8.

Ohio State Board of Medical Registration and Examination, Columbus, Dec. 8, 9 and 10.

Missouri State Board of Health, Southern Hotel, St. Louis, Dec. 14, 15 and 16.

Medical Council, Philadelphia, Dec. 15.

Medical Examining Board of Virginia, Lynchburg, Dec. 15-18.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Dec. 22, 23 and 24.

North Dakota Report.—The North Dakota State Medical Examining Board, at Grand Forks, October 6 to 8, held a written examination, at which 11 out of 14 applicants passed, a grade of 75 per cent. being required and questions being asked in 13 subjects.

Medical Organization.

California.

KERN COUNTY MEDICAL ASSOCIATION.—At the meeting held in Bakersfield, October 19, the society adopted the standard constitution and by-laws, and elected Dr. Clarence W. Kellogg, Kern, president; Dr. J. L. Carson, Bakersfield, vice-president, and Dr. William S. Fowler, Bakersfield, secretary.

SONOMA COUNTY MEDICAL SOCIETY.—The physicians of the county met at Santa Rosa, October 21, to consider the organization of a county society. Drs. Andrew W. Morton, Curtis G. Kenyon and Philip M. Jones, San Francisco, trustees of the Medical Society of the State of California, were present. Dr. Elizabeth M. Yates, Santa Rosa, was made temporary chairman, and Dr. Melville M. Shearer, Santa Rosa, temporary secretary. The standard constitution and by-laws was read, discussed and adopted, and permanent organization effected by the election of the following officers: Dr. Melville M. Shearer, president; Dr. James W. Jesse, vice-president; Dr. George W. Mallory, secretary, and Dr. Anabel McG. Stuart, treasurer, all of Santa Rosa.

Florida.

BREVARD COUNTY MEDICAL SOCIETY.—This society has been organized at Titusville with the following officers: Dr. Benjamin R. Wilson, Titusville, president; Dr. George W. Holmes, Sharpes, vice-president; Dr. William L. Hughlett, Cocoa, secretary and treasurer, and Drs. Leon A. Peek, Melbourne, Clyde P. Platts, Fort Pierce, and Edward E. Rollins, Titusville, censors.

Illinois.

CLARK COUNTY MEDICAL SOCIETY.—At the second quarterly meeting held in Marshall, October 8, a new constitution and by-laws was read and adopted.

LOGAN COUNTY MEDICAL SOCIETY.—This society met at Lincoln, October 29, adopted the standard constitution and by-laws and elected the following officers: Dr. James L. Lowrie, Lincoln, president; Drs. Louis F. Curtis, Elkhart, and Maskell Lee, Atlanta, vice-presidents; Dr. Harry S. Oyler, Lincoln, secretary, and Dr. William H. Kirby, Chestnut, treasurer.

Indiana.

GRANT COUNTY MEDICAL SOCIETY.—At the meeting held in Marion, October 27, the society adopted the standard constitution and by-laws. The increase in membership has been marked, especially among the younger physicians in the county.

Iowa.

GRUNDY COUNTY MEDICAL SOCIETY.—At its meeting held in Grundy Center, October 27, the society reorganized and adopted a new constitution and by-laws.

MUSCATINE COUNTY MEDICAL SOCIETY.—The full quota of officers of this society, whose reorganization was noticed in THE JOURNAL of October 24, is as follows: President, Dr. Henry M. Dean, Muscatine; vice-president, Dr. Calvin W. Smith, Muscatine; secretary-treasurer, Dr. Thomas F. Beveridge, Muscatine, and censors, Drs. George O. Morgridge, Muscatine, Alexander R. Leith, Wilton, and Channing B. Kimball, West Liberty. The next meeting will be held jointly with the Southeastern Iowa District Medical Association, at Muscatine, November 19.

Louisiana.

VERMILION PARISH MEDICAL SOCIETY.—The physicians of the parish met in Abbeville, October 17, and organized a society on the standard plan with 10 members, and the following officers: Dr. Milton R. Cushman, Abbeville, president; Dr. Joseph T. Abshire, Leroy, vice-president; Dr. Clarence J. Edwards, Abbeville, secretary, and Dr. H. B. White, Gueydan, treasurer.

ST. TAMMANY PARISH MEDICAL SOCIETY.—Physicians of the parish met in Covington, October 20, and organized a society on the standard plan, with the following officers: Dr. Ruffin B. Paine, Mandeville, president; Dr. James F. Pigott, Covington, vice-president, and Dr. H. D. Bulloch, Covington, secretary and treasurer. The society started with a charter membership of 11.

ST. JAMES PARISH MEDICAL SOCIETY.—Dr. Andrew G. Friederichs, New Orleans, councilor for the Second District, and Dr. Louis G. Le Beuf, New Orleans, met with the physicians of the parish at Convent, October 31, and aided in the organization of this society, which has an initial membership of 12. The following officers were elected: Dr. Pierre C. Tircuit, Oubre, president, and Dr. J. F. Buquoi, secretary.

TERREBONNE PARISH MEDICAL SOCIETY.—Dr. John M. Barrier, Delhi, president of the Louisiana State Medical Society, met the physicians of the parish at Houma, October 23, and participated in the organization of a parish society with an initial charter membership of 10. The following officers were elected: Dr. Robert E. McBride, Houma, president; Dr. Adolphe Delcourt, Houma, vice-president; Dr. Adolphe Delcourt, Jr., Houma, secretary, and Dr. Adolphe Tircuit, Little Caillou, treasurer.

IBERIA PARISH MEDICAL SOCIETY.—Dr. John M. Barrier, Delhi, president of the Louisiana State Medical Society, met the physicians of the parish at New Iberia, October 27, and helped them to organize a medical society with the following officers: President, Dr. George J. Sabathier, New Iberia; vice-president, Dr. George P. Minvielle, Jeanerette; secretary and treasurer, Dr. J. Wofford Saunders, New Iberia, and committee on scientific work, Drs. J. Wofford Saunders, New Iberia, Phares A. Bogkin, Jeancrette, and George P. Minveille, Jeanerette.

Minnesota.

MILLE LACS, ISANTI AND KANABEC COUNTY MEDICAL SOCIETY.—This society has been organized at Princeton with the following officers: President, Dr. Henry C. Cooney, Princeton; vice-president, Dr. Henry P. Bacon, Milaca; secretary, Dr. Theo. L. F. Armitage, Princeton; treasurer, Dr. G. Ross Caley, Princeton, and censors, Drs. Jacob F. Whiting, Spencer Brook, Robert B. Hixson, Cambridge, and George W. Nichols, Milaca.

Missouri.

MORGAN COUNTY MEDICAL SOCIETY.—This society, auxiliary to the Medical Association of the State of Missouri, was organized at Versailles, October 29, with the following officers: Dr. Joel D. Hubbard, president; Dr. John T. Beale, secretary, and Dr. Robert Q. Kelly, delegate to the state association, all of Versailles.

North Carolina.

SCOTLAND COUNTY MEDICAL SOCIETY.—Dr. Jacob F. Highsmith, Fayetteville, councilor for the Fifth District, met with the physicians of the county at Laurinburg, October 19, and organized a county society with the following officers: President, Dr. Daniel M. Prince, Laurinburg; vice-president, Dr. William T. Pate, Gibson; secretary and treasurer, Dr. Alfred W. Hamer, Laurinburg, and censors, Drs. Peter John, Laurinburg, William G. Shaw, Fontcol, and George M. Pate, Gibson.

Society Proceedings.

COMING MEETINGS.

Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 15.
Western Surgical and Gynecological Association, Denver, Dec. 28-29.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Proceedings of the Thirty-first Annual Meeting, held at Washington, D. C., Oct. 26 to 30, 1903.

(*Continued from page 1158.*)

Report of the Committee on Animal Diseases and Food.

DR. D. E. SALMON, Washington, D. C., chairman, presented this report, which will be published in full in THE JOURNAL. The committee concluded that it would require much work to decide with even approximate accuracy the proportion of human tuberculosis caused by animal infec-

tion; but the fact that 25 per cent. of the cases in children investigated by the German commission, and 50 per cent. of similar cases investigated by de Schweinitz showed that they were caused by animal infection was sufficient to convince the committee that measures should be taken and enforced at once to guard against infection from this source.

DISCUSSION.

Dr. George M. Sternberg called attention to the facts that pathogenic bacteria vary greatly in virulency, that attenuated varieties may be produced, motile bacilli lose their motility, etc.

Dr. Gardner T. Swarts, Providence, R. I., mentioned the shaking of the hide of the cow as a means of transmission of tuberculosis through milk, in addition to shaking the udder during the milking process.

Dr. John Guiteras, Havana, Cuba, said the results in Cuba tended to show the transmission of tuberculosis through milk was not as frequent as was generally supposed. No milk was used in Cuba that was not boiled, and yet he believed infantile tuberculosis was as frequent in Cuba as elsewhere.

Dr. J. M. Lindsay, Havana, Cuba, did not believe consumption, strictly speaking, was a contagious, infectious or hereditary disease. He said it was a product of wrong living. This wrong living might be from taking milk from tuberculous cows, or from living in a tuberculous house.

Dr. D. E. Salmon, Washington, D. C., said that while Cuba sterilized its milk more than America did, yet it might also be the case that if Cuba did not sterilize its milk it would have more tuberculosis than it did at present.

Report of the Committee on the Causes and Prevention of Infant Mortality.

Dr. Henry Mitchell, Asbury Park, N. J., chairman, in this report, said that among the most promising measures for a further reduction of infant mortality, the committee directed attention to the following: 1. To secure a more general adoption of cleanly methods of the collection, cooling and handling of cow's milk. It was not enough to destroy bacteria which had been permitted to gain entrance into the milk, or while pathogenic bacteria might be rendered innocuous, the toxins already formed were not affected by high temperature, hence no manipulation of the milk could be safely substituted for cleanliness in its collection and distribution. 2. To abolish breeding-places for flies in dwellings and to exclude them from contact with food. 3. To encourage the erection of improved tenements in cities and to show the dwellers in crowded districts the advantage of residence in the suburbs. 4. To more effectually isolate all cases of the dangerous communicable diseases.

Preparation of Vaccine Virus.

Dr. John F. Anderson, Washington, D. C., said experimental work had shown that the germicidal action of glycerin was feeble; other substances have been tried, and of these, chloroform seemed the most valuable. By it, the extraneous bacteria are removed in from a few hours to seven days; glycerin requires four weeks for full effect. Chloroform does not harm the vaccine potency. Chloroform, being extremely volatile, could be allowed to evaporate from the vaccine under aseptic precautions after being allowed to act as long as desired. It would be especially useful in hot countries where the active agent in vaccine does not retain its potency long, or when, as in epidemics, sudden calls were made for large quantities of virus.

Report of the Committee on the Disposal of Refuse Materials.

Mr. Rudolph Hering, New York City, read this report, pointing out that each municipality should select the most economical method in construction and maintenance, as determined by a study of its own special conditions, and by using the deductions of the large experience with such problems both in Europe and at home.

Report of the Committee on the Etiology of Yellow Fever.

Dr. John W. Ross, U. S. N., Washington, D. C., read this report. Baggage and bedding were admitted to Havana freely, and no cases were caused thereby. The conclusions previously reached were supported by experience since.

Report of the Committee on the Canteen in Armies.

Dr. George M. Kober, chairman, Washington, D. C., read this report. Reference was made to the introduction of the canteen system, and after dwelling at great length on the increase of drunkenness, the increase of trials by summary or other courts for drunkenness and for offenses caused by drunkenness, increase of desertions, increase in absence without leave, effects of the abolition of the sale of beer at the posts on the morality and discipline of the command, the committee presented the following recommendations:

THE RARE NECESSITY FOR ALCOHOL.

1. Your committee is aware of the fact that beverages containing alcohol are an accessory food of value only when it becomes necessary to increase temporarily the elasticity of mind and body and a desire and capacity for work, and that the subsequent depressing effects and the baneful influence of its misuse requires great care in its employment, especially when rest, proper food and some of the alkaloidal beverages, like coffee, tea, cocoa, and stimulants, like meat broths and soup, may accomplish the same purpose, and their sale as a substitute should be encouraged.

CHOOSE THE LESSER EVIL.

2. In spite of the fact that beer drinking, viewed in the abstract, is unproductive of good, your committee believes that its sale in canteens, under rational and comprehensive regulations, rather than its total prohibition, will subserve the best interest of scientific temperance, because so long as human nature is weak and the masses are not properly educated, the substitution of a lesser evil under military control appears not only justifiable but will in the future, as it has in the past, prevent excesses which are fatal to the soldier, soul and body. At present every effort toward total abstinence at military posts merely opposes theory to facts and sentiment to statistics, and compels recourse to saloons of the lowest character, whose proprietors care nothing for the efficiency of the army or the ruin of a good soldier.

A SOCIAL CLUB—NOT A SALOON.

3. Every precaution should be observed to conduct post exchanges and the sale of light wine and beer along the lines recommended by Munson in his "Theory and Practice of Military Hygiene," pp. 820-822, and your committee begs to emphasize the fact that the bar features should be entirely abolished and that the exchange should, in fact, be a soldiers' club, with ample facilities for reading rooms, legitimate amusements and athletic sports, where the soldier as a self-respecting individual may satisfy in an orderly manner his craving for diversion from the routine duties of a military life, without undue prominence of the refreshment feature.

SUBSTITUTES FOR ALCOHOLICS.

4. The sale of soft drinks, warm lunches, coffee, tea, cocoa, bouillon and soups should be encouraged as substitutes for alcoholic beverages, and medicinal and line officers should be directed to educate, by precept and example, the rank and file of the army; that, for persons in health, alcohol in any form presents no advantages not found in other foodstuffs or stimulants and which are, moreover, free from the dangers attending its use. In this connection it should be remembered that good food, well prepared and properly cooked and served, is one of the most effective prophylactic measures against the "drink habit" in civil as well as military life, and no effort should be spared to bring the culinary department in the army to the highest state of perfection.

VENEREAL PROPHYLAXIS.

5. Medical officers should point out the grave and far-reaching consequences of the effect of venereal diseases, so intimately connected with the drink habit, and make a strong plea in favor of continence. This may be done by letting these young men know that while the sexual passion is very strong it can be accelerated or delayed, excited or lowered by the influence of the will. The soldier can be assured that by the cultivation of pure thoughts, removal of temptation, normal mental and, especially, by vigorous physical exercise, continence is not only possible but easy.

OFFICERS SHOULD TAKE A PERSONAL INTEREST IN THEIR MEN.

6. Strong effort should be made to improve the social conditions of the soldiers. There are times and occasions when the friendly advice of a company commander or attending surgeon, showing a personal interest in the physical and moral welfare of the young soldier, will prove a greater benefit than the cold verdict of a summary court martial. Such personal efforts on the part of the officers, dictated by the spirit of a universal brotherhood of man, appears to us perfectly compatible with proper military discipline. It is also believed that the habit of making savings deposits with the army paymasters may be greatly stimulated by personal efforts.

RESOLUTIONS ADOPTED.

The committee recommended the presentation to the Senate and House of Representatives in Congress the following resolutions, which were adopted by the association:

Resolved, That this body deplores the action of Congress in curtailing the authorization of the army canteen or post exchange and, in the interests of general and military sanitation, recommends its establishment on its former basis at the earliest possible date.

Resolved, That this body, in the interest of temperance and humanity, cordially invites the intelligent co-operation of a very large element of good citizens, who have been active in securing legislation against the sales in the military service of alcoholics of any character, in taking successive steps toward the betterment of existing conditions, and thus assist in controlling and largely curtailing an evil which it is powerless at present to prevent.

Human and Bovine Tuberculosis.

DR. M. P. RAVENEL, Philadelphia, discussed the researches made on this subject. He felt that the genetic unity of the human and bovine races of tubercle bacilli, as well as their intertransmissibility, had been definitely demonstrated. It had also been proven that a certain proportion of persons, chiefly young children, met their death through infection with the bovine tubercle bacillus, but the knowledge at hand did not enable him at present to define the extent of this danger.

(To be continued.)

NEW YORK STATE MEDICAL ASSOCIATION.

Twentieth Annual Meeting, held in New York City, Oct. 19-22, 1903.

(Concluded from page 1159.)

Properties of the Blood Serum as Illuminated by Ehrlich's Researches.

DR. RICHARD C. CABOT, Boston, gave a most interesting talk on this subject, with the object of popularizing it among physicians. He characterized it as the most important single medical discovery that had been made since the publication of Virchow's cellular doctrine. After explaining, in a most delightful manner Ehrlich's side-chain theory, he went into the subject of hemolysis, with its medical and medicolegal aspects.

Diphtheria in the Country; Its Diagnosis and Management.

DR. J. R. STURTEVANT, Theresa, described cases from which he reasoned that the admission of chickens to the dwelling house and the open cesspool near the door were not uncommon sources of diphtheria. He believed it was the duty of every country practitioner to always keep diphtheria antitoxin at hand, and, according to his own experience, doses of 1,500 units were ordinarily sufficient.

DISCUSSION.

DR. J. ORLEY STRANAHAN, Rome, said that he had found it necessary and desirable to use large doses; in one case he had given 3,000 units every six hours for five doses before there was any improvement.

DR. DELANCEY ROCHESTER, Buffalo, said that an extensive hospital experience with diphtheria had taught him to use antitoxin freely. His initial dose was 4,000 units at least, and he had given during the first year of life as high as 5,000 units, sometimes repeating this dose in three hours.

Some Features of the Epileptic Attack.

DR. B. ONUF, Sonyea, called attention to the fact that the epileptic cry was not shrill, but was a low tremulous moan. The positions of the limbs varied in different attacks or even in the same attack, but the point to be noted was the asymmetry of these postures. It was not always easy to determine whether or not any consciousness remained, but there might be some recollection of the attack, or if pricked with a pin during the seizure, the way in which the limb was placed out of the way of the irritation might show some cerebral activity to be present.

Prostatectomy.

DR. PARKER SYMS, New York, reported 25 cases and showed the specimens. There was one death, which occurred after 23 operations had been done. There were practically 20 cures. The principal danger was from the anesthetic.

DISCUSSION.

DR. GOODFELLOW, San Francisco, said that he had done about 90 prostatectomies. He makes use of the old median lithotomy operation, and, in the past two years, in order to avoid the dangers of ordinary general anesthesia, he has employed spinal cocainization. He rarely had much hemorrhage with these perineal operations, and since he had, as far as possible, avoided instrumentation, both before and after operation, epididymitis had been a very rare complication.

DR. HENRY ROTH, New York, said that he had seen most of Dr. Syms' cases, and had been impressed with the fact that the mortality was only 4 per cent., whereas the earlier prostatectomies of a few years ago had a mortality of 30 or 40 per cent. The general condition rather than the patient's age should be considered when deciding on operation.

Knowledge of the Eye That is of Use to the General Practitioner.

DR. S. BUSBY ALLEN, New York, read this paper. He said that every practitioner should be on the alert for acute glaucoma because he could easily detect it by merely noting the tension of the eye, and because a failure to recognize the true condition at once led to such serious consequences. In about 30 per cent. of cases of tabes progressive loss of vision, diplopia and possibly ptosis precede the other symptoms. The onset and steady increase of presbyopia at an unusually early age should suggest diabetes. Cataract is also not uncommon in diabetes. Inequality of the pupils should always lead to a searching examination.

The Early Diagnosis of Tuberculosis.

DR. JAMES J. WALSH, New York, was the author of this paper. He pointed out that a rapid pulse was often persistently present for a considerable time before the toxin of tuberculosis exerted any perceptible influence on the body temperature. And yet slight temperature variations were among the early signs. The temperature should be taken at 8 a. m., 12 m. and 6 p. m., and if there is a daily variation of a degree and a half it is probable that some infection is present. In some healthy individuals a morning temperature of 98.5 F. would point to a slight elevation of the temperature. There was often extensive consolidation of the lungs, and sometimes even secondary infection before tubercle bacilli appeared in the sputum. The posterior portion of the apex was the first part usually affected.

DISCUSSION.

DR. DELANCEY ROCHESTER mentioned a case in which there was not as much as one degree of daily variation in temperature, so far as could be learned from taking the temperature three times a day, but when he had it taken every two hours from 6 a. m. to 10 p. m. it was discovered that the highest temperature was between 8 and 10 p. m., instead of between 2 and 6 p. m., and that the total daily variation was 2.5 F. He had found a change in the pitch on percussion to be of value at a time when the other physical signs were negative. The physical signs of incipient tuberculosis were often obtained at the clavicle, above the scapula and in the upper part of the scapular region. The tuberculin test is an important confirmatory test.

DR. S. A. KNOPF, New York, said that early pulmonary consolidation could often be detected best by placing the hand over the lung and telling the patient to take a deep breath and then make a humming sound. This would produce a perceptible fremitus. He had known reaction to the tuberculin test in chlorotic girls, as well as in actinomycosis and syphilis; moreover, it sometimes causes a generalization of the disease; hence it is both unreliable and dangerous.

Treatment of Septic Affections by the Intravenous Injections of Collargol.

DR. GEORGE TUCKER HARRISON, New York, recommended injection of a 5 per cent. solution into the vein under aseptic precautions; he had never found it necessary to use more than 7 injections in any one case. He felt that this treatment was a therapeutic resource of the highest order.

Acute Cholecystitis.

DR. J. H. MUSSER, Philadelphia, believed cholecystitis to be a very common disease and one bearing some resemblance to appendicitis. Pain in the epigastrium, or radiating to the right shoulder, was present in 95 per cent. of the cases. Forty per cent. of all types of cholecystitis die if not operated on, whereas only 5 per cent. die if subjected to operation during the course of the disease.

DISCUSSION.

DR. ROBERT T. MORRIS, New York, mentioned a case in which, although there had been no prodromal symptoms immediately following an operation for acute empyema of the gall bladder, the patient passed through a typical typhoid. He believed acute pancreatitis to be a most dangerous complication, this alone affording an excellent reason for operating.

DR. ALEXANDER LAMBERT said he had found it at times wellnigh impossible to differentiate between appendicitis and chole-

cystitis. Some assistance was derived from noting the effect of pressing over the appendix and over the gall bladder.

The Surgical Treatment of Salpingitis.

Dr. Henry C. Coe, New York, said that the propriety of the operation of vaginal incision and drainage in pyosalpinx is now generally recognized. Even the simplest cases of pelvic abscess should be prepared for an abdominal section before any attempt is made to evacuate them. The practical difficulty in all conservative operations on the tubes was to distinguish between healthy and diseased tissues. When doing the radical operation, it was better to excise the tube and suture the uterine cornu than to leave a stump of tube.

The Non-Operative Treatment of Salpingitis.

Dr. W. Travis Gibb, New York, said that in acute catarrhal salpingitis the treatment should be largely expectant, and the use of antipyretics should be avoided, because pain and fever were depended on by the physician to show him the course of the disease. Curettage and intra-uterine applications should be avoided during the acute stage. As a symptomatic cure can be effected in many cases of chronic salpingitis by non-operative treatment, this method should be given a fair trial. Opiates and stimulants should be avoided and everything done to improve the general health. In addition large hot saline douches should be taken, and the vagina should be tamponed with cylinders of lamb's wool moistened with ichthyol.

DISCUSSION.

Dr. W. M. Polk spoke in favor of incision through the posterior cul-de-sac in cases of severe pelvic inflammation.

Dr. C. Bonifield, Cincinnati, said that he had found veratrum viride, given usually in doses of 8 to 15 minims every eight to twelve hours, a most useful means of limiting pelvic inflammation, and at the same time favoring elimination of septic matter by stimulating the skin, kidneys and liver.

Clinical Aspects of Ileocolitis in Children.

Dr. Thomas M. Rotch, Boston, said that ileocolitis was usually secondary to fermental diarrhea or to the acute infectious diseases, especially measles. The characteristic symptoms were persistent fever, frequent, small stools containing blood, mucus, pus and shreds of membrane, tenesmus and more or less abdominal tenderness. Of 61 cases of diarrhea in which bacteriologic examinations were made last summer, the *Bacillus pyocyaneus* was present as the apparent cause in 2, the *Streptococcus pyogenes* in 1, and the Shiga bacillus in 10 cases. In the remaining 48 the sugar-fermenting organisms were found. The Shiga bacillus was not always the cause in cases having slightly bloody stools.

Dr. Albert H. Ely, Southampton, reported several cases of colon bacillus infection of the female genito-urinary tract.

DISCUSSION.

Dr. William H. Park said that the more ileocolitis resembled severe dysentery, the greater the probability of finding the dysentery bacillus in the stools.

Dr. L. Emmett Holt, New York, said that all kinds of lesion had been found associated with the Shiga infection. Such infection was commonly denoted by sudden onset, high temperature and stools of blood and mucus. In these cases it seemed probable that the serum treatment would prove of service.

Dr. R. G. Freeman, New York, said that in most of the 44 cases in which he had found the Shiga bacillus there were stools of blood and mucus. The stools and the persistence of the disease were the most characteristic features. The mortality was a trifle higher in the cases that did not receive the serum treatment, but the difference was slight. It was probable that the dosage had been inadequate.

Other papers were read as follows:

"Arteriosclerosis and Its Bearing on Certain Lesions of the Retina and Optic Nerves," by Dr. Charles Stedman Bull, New York. "The Influence of Oxygen Taken by Full Normal Respiration, When Chemically Pure, as a Means of Sustaining and Increasing Mental, Nervous and Physical Energy," by Dr. Cordelia A. Greene, Castile. "Peculiar Symptoms Following a Radical Operation on the Ear," by Dr. George F. Cott, Buffalo. "Radium in Medicine," by Dr. Samuel G. Tracy, New York. "The Etiology and Pathology of Salpingitis," by Dr. Edward J. Ill, Newark, N. J. "Removal of Superior Maxillæ for Phosphorus Necrosis," by Dr. David P. Austin, New York. "The Typhoid Epidemic in Ithaca, with Special Reference to Causation, Prevention and Treatment," by Dr. Chauncey P. Biggs, Ithaca. "Treatment of Compound Fractures," by Dr. V. D. Bozovsky, Dunkirk. "Minus Cylinders; Those Who Prescribe Them and Those Who Wear Them," by Dr. Frank W. Higgins, Cortland.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Zinc Sulphocarbolate in Cholera Infantum.

Dr. W. F. Waugh, in an abstract in *Med. Rev. of Reviews*, lauds the use of zinc sulphocarbolate in the treatment of summer complaint, enterocolitis and cholera infantum. The bowels should be thoroughly cleared out with castor oil, calomel, mercury and chalk, aromatic rhubarb, lavage or colonic flushing as seems best in the individual case.

For lavage he recommends a solution containing one grain of zinc sulphocarbolate to the ounce. The same solution may be used for colonic flushing.

When the type is dysenteric, silver nitrate, grains 2 (.12) to the pint (480.) of water should be used for rectal flushing and should be given as hot as can be borne. This should be followed with the zinc salt internally, grains ½ (.03) to two (.12) every hour to children in the second summer. It should be given in powder form combined with bismuth and pepsin. Where there is extreme acidity of the stools marked by excoriation of the rectal mucosa, sodium sulphocarbolate is preferable or the triple salts zinc, sodium and calcium.

Atropin may be of service in relieving the gastric irritability. The best diet, according to the author, is the raw white of egg in ice water, coffee, rice-water, barley water, toast water, followed by meat soups and fruit juices. The fresh juice of lean beef can be given in five (.30) to ten (.65) drop doses every hour, and in extremely debilitated individuals it should be dropped on the tongue and allowed to trickle down the esophagus.

Hot, cold or salt baths are always indicated.

Chronic Otorrhea.

The following combination is recommended by *Merck's Archives* in the treatment of chronic otorrhea:

℞.	Ichthyol	|
	Glycerini	|
	Aq. destil., āā.....3ii	8|

M. Sig.: After thoroughly syringing out the ear with warm chamomile tea, allow four to eight drops to run into the ear and repeat this treatment once a day.

The treatment of chronic nicotinism involves hygienic and medicinal measures, according to J. V. Shoemaker, in *Med. Standard*. The victim should abandon the use of tobacco. If he can not do this, he should at least diminish his smoking or chewing. His food should be plain, well prepared, nutritious and digestible. Tonics and digestants are usually required. The following combination is of service:

℞.	Zinci valerianatis .....gr. ii	12
	Zinci phosphidi .....gr. ⅛	008
	Pulv. cannabis ind. .....gr. ¼	015

M. Ft. capsula No. i. Sig.: One such every four hours.

The salts of zinc counteract the nervous prostration and the cannabis indica allays the morbid imagination, which sometimes continues for a considerable length of time after the use of tobacco has been stopped.

Erysipelas.

The constitutional treatment of erysipelas, according to Hyde, should be directed to lowering the temperature, to obtaining the proper functional activity of all the organs of the body and to sustaining the strength of the patient. The purpose of local treatment is to limit the extension of the disease. Collodion, iodin, carbolic acid, alcohol, solutions of tannin and nitrate of silver are among the various remedies

recommended as local treatment for this infection. The following combinations have been employed with success:

℞. Sodii hyposulphitis 3iii 12
Aquæ .....ʒiii 90
M. Sig.: Apply locally on gauze; or:

℞. Acidi carbol. 3ii 8
Alcoholis .....ʒiss 45
M. Sig.: Apply locally.

The following combinations are remedies which have been used successfully by experienced physicians, as noted by Cheron in a former issue of *Ther. Gaz.:*

℞. Creolin 3i 4
Iodoformi 3iv 15
Lanolini 3x 40
M. Sig.: Thoroughly spread over the affected area and cover with gutta percha; or:

℞. Creolin 3i 4
Cretæ prep.
Adipis, āā .....ʒss 15
Olei menth. pip. .....gtt. iii 20
M. Sig.: Apply locally.

The foregoing serves to produce a cooling effect to the inflamed parts.

Ichthyol may be used as a local antiseptic in the following combination:

℞. Ichthyol
Spts. etheris, āā.....3v 20
Collodii (flexible) 3x 40
M. Sig.: Apply locally.

Internally the administration of quinin is of value to check the progress of the disease and to reduce the temperature. Iron may be given internally in the form of the tincture in large doses frequently repeated and well diluted in water. Locally it may be applied as follows:

℞. Ferri sulphatis 3i 4
Lig. petrolati .....ʒi 30
M. Sig.: Apply locally.

The sodium preparations, applied on compresses, may be combined as follows:

℞. Sodii salicylatis 3ii 8
Sodii bicarb. 3i 4
Aq. bullientis .....Oi 480
M. Sig.: Apply on compresses.

The tincture of benzoin has frequently been used in the following combination:

℞. Tinct. benzoini comp.
Glycerini
Collodii (flex.), āā.....3ii 8
M. Sig.: To be painted over the affected area once or twice daily.

Internally the following combination containing ammonium is recommended:

℞. Ammon. carb. 3ii 8
Solutionis ammon. acetatis .....ʒiii 90
Ext. glycyrrhizæ flu. .....ʒi 30
M. Sig.: Two teaspoonfuls every three hours in water.

Delirium Tremens.

The treatment of delirium tremens, according to J. R. Clemens, in *N. Y. and Phila. Med. Jour.*, consists in prophylaxis and the treatment of the attack. The abortive treatment should be directed toward proper elimination by the bowels, moral suasion and feedings of milk and beef juice every two hours, with some sedative such as sulphonal or paraldehyde. An attack may develop a lobar pneumonia, causing one to consider the question as to the advisability of administering alcohol in delirium tremens. Alcoholics, as a rule, do not eat a sufficient amount of nourishing food, therefore food, according to the author, is the chief indication in the treatment. And, if the patient is well along in years or the attack is severe, he recommends the administration of whisky or brandy first as a bribe to get the patient to take food, and, secondly, as a stimulant to the heart, which will also combat the insomnia which is so constant. In young subjects both narcotics and alcoholic stimulants are contraindicated. The general treatment, as outlined by the author, is as follows:

FOOD.

Milk, raw or peptonized, every two hours, alternating with beef juice.

MEDICINAL TREATMENT.

A dose of the mild chlorid of mercury at the onset, followed by a saline. A bitter tonic containing strychnia as the chief ingredient should then be given, and if the heart sounds become weak the strychnia should be given hypodermically. In treating the stubborn insomnia, the room should be dark, cool and quiet. To promote sleep hyoscin hydrobromate in doses of gr. 1/200 (.0003) to gr. 1/100 (.0006) should be given hypodermically or it may be substituted by sulphonal or paraldehyde. He condemns the use of opium or chloral because of the condition of the heart and kidneys. The patient should be constantly observed because of the tendency to suicide. Moral suasion should be used to keep the patient in bed, and, if necessary, a draw sheet should be passed across the bed over the patient and tied to the bed railing. The treatment of the delirium should be secondary to the heart and lungs.

Dr. George S. Weever, in the same periodical, recommends the following preparations either separately or combined in the treatment of the insomnia: Ammonium bromid dram 1 (4.00); morphin sulphatis grain ¼ (.015); chloral hydrate grains ten (.65) to grains fifteen (1.00). He prefers the ammonium preparation along with cold douches and packs to relieve the delirium. After the patient has recovered from the delirium the following combination is recommended:

℞. Quin. sulph.
Pulv. capsici, āā..... gr. ii 12
Ext. nucis vom. .....gr. ¼ 015
M. Ft. cap. No. i. Sig.: One every four hours.

If the stomach is irritable, as is usually the case, H. K. Glidden recommends the following:

℞. Bismuthi subnit.
Cerii oxalatis, āā.....3i 4
Sodii bicarb. .....gr. xxiv 1 65
M. Ft. chartulæ No. xii. Sig.: One powder every four hours.

Medicolegal.

SOME LEGISLATION OF THE YEAR 1903.

Illinois—Restricts Sale and Prescribing of Cocain.—What is to be known as Section 14a of the act to regulate the practice of pharmacy in Illinois is added by an act in the laws of 1903. It provides that it shall not be lawful for any druggist or other person to retail or sell or give away any cocain hydrochlorate, or any salts of or any compound of cocain, or any preparation containing cocain, or any salts of or any compound thereof, except on the written prescription of a licensed physician or dentist, which prescription shall only be filled once, and must have written plainly on it the name and address of the patient. This section shall not apply to sales at wholesale by any manufacturer or wholesale dealer, who shall sell original packages only. Each container must be labeled with a label specifically setting forth the proportion of cocain contained therein. What is to be known as Section 14b, provides that any druggist or other person who shall retail or sell any cocain, etc., in violation of this act, and any druggist or other person who shall prescribe any cocain, etc., to any person addicted to the habitual use of cocain, etc., in any form, shall, for the first offense, be fined from $50 to $200, and for each subsequent offense from $200 to $1,000, and if the person so offending shall have a license as a physician, dentist or pharmacist, such license shall be revoked. (The words "knowingly prescribes" do not appear. The physician apparently has no escape in case he fails to recognize a patient as a cocain user.)

Illinois—Must Report Deaths as Well as Births—Fees.—The Illinois act of 1903, referred to on page 971 of The Journal, Oct. 17, 1903, as requiring reports of births, also provides that it shall be the duty of every physician and midwife practicing in the state to report in writing, to the State Board of

Health at Springfield, the death of any of his or her patients within thirty days after said death: Provided, That in the case of deaths which occur within the corporate jurisdiction of cities, the ordinance of which requires that the burial or removal permit shall be issued before the burial or removal of the body, and that before such permit shall be issued a report or certificate of death shall be presented to the official by whom the permit shall be issued, no report need be made to the State Board of Health by the physician or midwife. All reports of deaths shall be made in the manner directed by the State Board of Health on its blank forms. Every physician, midwife or coroner who shall make a report of death to the State Board of Health in the manner provided for shall be paid for each report the sum of 25 cents. The fees for reporting births or deaths are made a charge on the county in which they accrue, and the county clerk of the respective counties shall, on the request of any person entitled to said fees in his county, issue to such person his warrant on the county treasurer of said county for the amount of fees due such person under this act, and the county treasurer of said county shall pay the same on presentation out of any money belonging to the county not otherwise appropriated: Provided, That no payment shall be made under the sections providing for payment for reporting births and deaths where the period of gestation is less than seven months.

Maine—Prohibits Spitting on Floors of Street Cars.—Chapter 139 of the Public Laws of Maine of 1903 provides that whoever spits on the floor of any street car shall be fined not less than $2 nor more than $10.

Maine—Provides for State Laboratory of Hygiene.—Chapter 223 of the Public Laws of Maine of 1903 confers on the State Board of Health authority to establish and equip with proper and necessary apparatus, instruments and supplies a state laboratory of hygiene for the chemical and bacteriologic examination of water supplies, milk and food products, and the examination of cases and suspected cases of diphtheria, typhoid fever, tuberculosis, glanders and other infectious and contagious diseases. The State Board of Health shall appoint a director of such laboratory, who shall hold that position at the pleasure of the board. He shall keep a record of all specimens sent to him for examination, and examine these specimens without unnecessary delay, and do such other work and make such other investigations relating to the public health as the board may from time to time instruct him to do. The services of the laboratory and all investigations therein made shall be free to the people of the state.

Massachusetts—Practice of Dentistry by Physician.—Chapter 219 of the Acts of Massachusetts of 1903, entitled "An act relative to the practice of dentistry," amends Section 29 of Chapter 76 of the revised laws so that it reads: The provisions of Sections 24 to 28, inclusive, shall not apply to a physician registered under the provisions of this chapter "and in actual practice as a physician, in cases where he deems immediate treatment necessary for the relief of his patients," etc., the amendment consisting of the insertion of the words inclosed in quotation marks.

Massachusetts—Forbids Furnishing Liquor at Hospitals.—Chapter 410 of the Acts of Massachusetts of 1903 provides that whoever gives, sells or delivers spirituous or intoxicating liquor to a patient of the Massachusetts Hospital for dipsomaniacs and inebriates, or of any of the state hospitals for the insane, or to a patient under the control of any of said hospitals, except under the direction of a physician of the hospital, and whoever has in his possession within the precincts of any of said hospitals, any such liquor, with intent to convey or deliver it to any patient thereof, except under direction as aforesaid, shall be punished by a fine of not more than $50 or by imprisonment for not more than two months.

Michigan—Prohibits Exhibitions of the Deformed, Etc.—No. 103 of the Public Acts of Michigan of 1903 provides, under penalty, that it shall be unlawful for any physician or other person to expose or keep on exhibition any human monstrosity, or any diseased or deformed human bodies, or parts or representation thereof, which would be indecent in the case of a living person, except as used for scientific purposes before members of the medical profession or medical classes.

Michigan—Provision for Prevention of Rabies.—No. 116 of the Public Acts of Michigan of 1903 provides that whenever it shall be proved to the satisfaction of the local board of health that any indigent person within its jurisdiction has been bitten by a rabid dog, or other rabid animal, or in any other manner has been infected with the virus of rabies, said board shall make the necessary arrangements and send said person to the Pasteur Institute at the University of Michigan. The necessary expenses thus incurred shall be a charge on the township, city or incorporated village in which the expense was authorized. Before their payment or allowance all bills for such expenses shall be audited by the local board of health.

Wisconsin—Maternity Home and Baby-Farm Regulations.—Chapter 161 of the Laws of Wisconsin of 1903 provides that any person or corporation who own, conduct or manage any institution for the boarding or sheltering of infant children, or any so-called maternity home or lying-in hospital or so-called "baby farm" shall, before taking any inmate, report in writing to the local board of health, health officer or health department, the name and address of such person or corporation and the exact location of the institution. The local health officer or health commissioner, or his assistants, shall, at reasonable hours, be admitted to inspect the institution. Births, including those of stillborn or prematurely born children, taking place in such maternity home shall be reported to the local board of health or health officer or department within twenty-four hours and before the child is removed from the institution. Likewise, the arrival of any child at a home for infants shall be reported, giving name, sex, age, color and from whom received. The removal of any child shall also be reported. And it shall be the duty of the local board of health, health officer or department to keep informed of the nature and reputation of every such institution in their respective jurisdiction, and to visit and inspect the same from time to time.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.
October 31.

1 *The Dietetic Treatment of Chronic Nephritis. J. M. Anders.
2 *The Technic of McGraw's Method of Gastroenterostomy. Samuel Lloyd.
3 Successful Intraneural Infiltration of the Median and Ulnar Nerves During an Operation for Dupuytren's Contraction of the Fingers. W. W. Keen.
4 *Digestion of Milk. George Richter.
5 *Mercury; Its Administration Hypodermically in Syphilis. William F. Bernart.
6 *Volvulus of the Stomach. C. D. Spivak.
7 *Multiple Visceral Lesion. A. L. Benedict.

1. **Chronic Nephritis.**—Anders considers the diet most important. He thinks clinicians tend too much to giving an insufficient amount of albuminous aliment, and finds a moderate quantity allowable and often beneficial. He is not inclined to think the red meats especially more dangerous than the white. In general he would say that whole milk diluted should make a considerable portion of the diet, while the meats should be restricted as a rule, and fruits, green vegetables and rice be given more freely. The individual meals should be small and taken at three-hour intervals. The extent to which the diet contributes to nutrition should be carefully estimated, as shown by noting the effect on the intensity of the albumin and particularly on the kidney elimination of normal metabolic products. He does not recommend chemical substances as tests for secretory function. The use of cryoscopy to determine the kidney secretion is specially mentioned. The patient should keep a careful record of the body weight at intervals and the diet be regulated accordingly. He also insists on the value of systematic blood examinations.

2. **The McGraw Method of Gastro-enterostomy.**—Lloyd describes the McGraw operation, using the illustrations employed

in Walker's paper in THE JOURNAL of January 17. He believes in a good-sized rubber ligature, and he thinks Willy Meyer's suggestion of using a 4 mm. rubber cord should be adopted. He has had 7 cases, with no deaths, operated on thus. Six were successfully carried through by the McGraw method, but in the seventh, operation was completed by suturing on account of the breaking of the rubber. He does not think, however, that the method would be applicable in entero-enterostomy necessitated by complete intestinal obstruction.

4. **Digestion of Milk.**—Richter argues for the use of preservatives in milk, claiming that an overdose of an antiseptic is not so harmful as infected milk, and that the absolute forbidding of these preservatives, formaldehyd, boric acid, etc., is illogical and detrimental to the health of the community.

5. **Mercury in Syphilis.**—Bernart holds that the hypodermic method of using mercury in syphilis will cure many cases which under other methods are known as incurable, and will place the treatment on a more scientific basis, and allow the keeping of better and more accurate records. This method is, he says, absolutely essential in syphilitic lesions of the nervous system, still amenable to specific treatment. Here will be found its greatest field. He insists on the importance of accessory treatment; thorough cleanliness of the teeth and mouth, regulation of the diet, abstinence from alcohol, the observance of strict hygienic conditions, outdoor exercise, fresh air, sunshine and baths. The method he uses is to inject in the post-trochanteric region, the dosage varying within certain recognized limits to suit the individual. The principle in the severe cases is to give the largest dose possible without producing ptyalism.

6. **Volvulus of the Stomach.**—Spivak reviews and reproduces cases and discusses the mechanism. Parts of his conclusions are as follows:

Volvulus of the stomach occurs in all ages and in both sexes.

Digestive disorders may be considered as etiologic factors.

Volvulus of the stomach may be divided into (*a*) that due to organic changes produced by adhesions, ulcerations, tumors and contractions, and (*b*) that in which no visible organic changes have taken place.

The characteristic symptoms are: Sudden onset; distension, which commences in the left hypochondriac region, and which gradually increases in size; a tumor, which gives, on percussion, a tympanitic sound; vomiting or regurgitation immediately following ingestion of food or drink; no belching, no escape of flatus; inability to pass a sound into the stomach.

When the condition is recognized, early operative interference is indicated, and recovery is almost certain.

7. **Multiple Visceral Lesion.**—This term is used by Benedict to imply disease where the heart, liver and kidneys are chronically inflamed, the degenerative lesions being more or less interdependent. He includes them in the digestive specialty on account of the importance of nutrition of these patients, and of the important diagnostic problems as regards the size of the liver, the acidity of the urine, blood and stomach contents and the fact that sometime in their course the actual treatment must be mostly directed to the digestive organs. In many instances the liver is more affected than the heart and kidneys, and the liver itself is quite directly dependent on the dyspeptic troubles. He mentions the importance of diet, regulation of the amount of water, etc., and remarks that enteroclysis, aside from its local influence in the removal of toxins, has its value as a cardiac and circulatory stimulant and is one of the best means of treating the renal element of multiple visceral lesions. Saline solution is one of the most harmless and efficient diuretics; similarly gastric lavage is valuable. He does not think that hypodermoclysis or intravenous injections are necessary in these cases unless the state of the bowel prohibits enteroclysis. The hemorrhages which may occur from varicosities due to back pressure in the portal system are remarked on, and also that the pancreas is likely to participate in the sclerotic process involving the liver. The condition of the blood and ductless glands must also not be neglected.

October 31.

8 Presidential Address to the Medical and Chirurgical Faculty of Maryland. Eugene F. Cordell.
9 *Conservative Gynecologic Surgery; Its Practical Results. Henry C. Coe.
10 *The Diagnosis of Head Injuries. Clinton B. Herrick.
11 The Treatment of Diseased Faucial Tonsils in the Adult. Eugene W. Davis.
12 *The Present Status of Spinal Subarachnoid Cocainization. Ernest G. Mark.
13 *A Consideration of the Pathology and Treatment of Cancer. Leonard Weber.

9. **Conservative Gynecologic Surgery.**—Coe notices the methods of different operators, with special reference to results. In over 5 per cent. of his conservative operations he has been obliged to perform a secondary laparotomy in order to effect a cure, and he thinks this fairly represents the experience of other surgeons. Those who have employed the vaginal route report better results, but one can not accept the sweeping statement of Joseph Price that the necessity for a second operation implies a want of skill or technic in the first. The results of conservative surgery of the adnexa have their drawbacks, and we have not yet discovered any certain methods of preventing the re-formation of adhesions or predicting what cases will give further trouble. He does not, as a rule, favor resection of the tubes. He thinks it rather an unnecessary procedure, and as regards relief of symptoms from conservative operation, the results may be disappointing. What the patient generally wants is relief from pain and she will be disappointed if this is not obtained. Disturbances of menstruation are common after partial removal of the ovaries, amenorrhea, but more often profuse menorrhagia. He has been obliged to remove the uterus at least in a dozen cases on account of hemorrhage alone. His results in cure of sterility have not been so brilliant as those reported by Dudley, since less than 3 per cent. of his patients have become pregnant after resection of the tubes and organs. While he believes in the propriety of preserving the ovaries even at the risk of a second operation, the question must suggest itself as to whether it is not better to leave a doubtful ovary alone than to tinker with it, and thus possibly invite cystic degeneration or the cirrhosis which we fear. We can not exactly define the border line between normal and pathologic, even on the operating table. Conservatism, however, has come to stay, and with more perfect technic and experience better results may be hoped for.

10. **Head Injuries.**—Herrick describes the various forms of head injuries, including contusions, scalp wounds, fractures of various types, contused brain, lacerations, hemorrhage, etc.

12. **Spinal Cocainization.**—Mark has investigated this subject, sending a circular out to the various surgeons, most extensive users of spinal cocainization, asking them concerning mortality attributed to it, the technic, and the dangers as compared with general anesthesia. He reviews the deaths reported and finds little evidence of the responsibility of the method for the result. Only one surgeon heard from has abandoned the method on account of the "difficulty of obtaining uniform sterile solutions of strength"; some preferred tropacocain to cocain. A number of cases are reported. He concludes that the method is as safe, if not safer, than general anesthesia, and that we may safely employ a dose up to .48 of a grain of cocain without fear of toxic effects, and that shock, when present, is decidedly less than that of general anesthesia. There is less danger of annoying sequelæ, but on account of the variability in the length of its analgetic action, it is contraindicated in prolonged operative procedures. Only one death has been reported in this country that could be attributed to its use, and the patient was an elderly woman, weighing 318 pounds, with a very serious heart lesion. The surgeon in this case, Dr. Morton, is still one of the most devoted adherents of the method.

13. **Cancer.**—Weber does not implicitly accept the parasitic theory of cancer. The parasite has not been demonstrated. Early excision is the method to be employed. He has given up escharotics and advises against them. The use of the *x*-ray should follow the operation. In many cases much can be done by diet, hydrotherapy, sunshine, tonics, etc., to increase the resistance and prevent recurrence.

14 *The Relation of Laboratory Research to the General Practitioner of Medicine. Horace D. Arnold.

15 Pneumothorax Associated with Fracture of the Ribs; Report of Two Cases. Fred T. Murphy.
16 *Some Observations on X-Ray Therapeutics in Skin Diseases. Frederick S. Burns.
17 *Record of Parasitic Infections in the Philippines. W. J. Calvert.

14. **Laboratory Research and the General Practitioner.**—The importance of laboratory methods is insisted on by Arnold, who, nevertheless, points out that it is one of the faults of our medical education at the present day to produce an exaggerated view in the mind of the medical student as to the importance of this work in general practice. He says it requires some courage to say that this side of medical education is overdone in schools, but the observation of recent graduates and students has convinced him that such is the case. While the laboratory expert has a better foundation he has also laboratory astigmatism, and common sense may be lacking. He thinks the general practitioner should have certain laboratory methods at his command, counting of the blood corpuscles, estimation of hemoglobin by means of Tallquist paper, examination of the urine, sometimes of the feces, sputum, pus, vomitus, and the gastric contents. The Widal reaction is rather beyond the general practitioner at present, and the laboratory should be depended on, but the bacteriologic diagnosis of diphtheria is important. He sums up by saying that the laboratory method in clinical medicine is of acknowledged value and such measures are not employed by the general practitioner as fully as they should be. The man who has plenty of time and does not choose to equip himself is short-sighted. The man who thinks he is too busy would find a limited sacrifice of time one of the best investments he could make. The practitioner who is too busy with general practice to do such work himself should have it done, nevertheless, where necessary.

16. **The X-Ray in Skin Diseases.**—Burns finds the *x*-rays of great value, in epithelioma especially, and says they offer the best relief to a certain class of such lesions. Some cases are better treated by excision and it is a waste of time to treat very small lesions for weeks when they can be effectually destroyed in a few minutes with the curette and cautery. Epithelioma and carcinoma below the cutaneous surface, and even lesions which have become deep by infiltration from the skin, should not be treated by the *x*-rays with the hope of cure. All such cases in which he has tried them have been failures and without permanent benefit, but there is almost a constant temporary relief from pain and sometimes considerable improvement in the general condition. The permanency of cure of epithelioma may be questioned, though he has not yet seen any relapses in his cases. He mentions cases of lupus, scrofuloderma, folliculitis of the beard, psoriasis and eczema treated with success. His experience includes 150 cases of skin disease treated by *x*-ray therapy.

17. **Parasitic Infections in the Philippines.**—In 136 autopsies Calvert found 53 cases of parasitic infections, 29 of ascarides, 10 of ankylostoma, 13 of tricocephalus and 1 of tenia. Forty of these cases were single infections, namely 25 of ascarides, 5 of ankylostoma, 9 of tricocephalus and 1 of tenia. Five were double infections of 2 or more; one was a triple infection of all three parasites. He says, considering the customs of the natives, especially as regards their drinking water, the figures are not so high as one would at first suppose. The small number of tenia is surprising when it is considered that cysticercus exists in 4 per cent. of all the hogs killed in Manila. No cases of trichiniasis were observed. Five cases of filariasis were found all from the Island of Luzon.

21 *Some Notes on a Diet of Bread and Fruit, and Its Effects on High Blood Pressure, Dropsy and Obesity. Alexander Haig.
22 *Hallux Valgus. John G. Sheldon.

18. **High Frequency Currents.**—Piffard describes his methods and apparatus and their advantages. The article does not lend itself well to abstracting as regards the first point, and should be consulted for a full understanding.

19. **Gastric Juice Activity.**—Two new diagnostic methods are described by Bettmann and Schroeder, one based on the fact that albumin in solution will foam when shaken up, and if a digestive ferment be mixed with the foam the albumin will be digested and the foam will disappear, and with a rapidity in proportion to the amount of digestive ferment added. The results of this test agree with the law of Borissow and Schütz that the rapidity of the digestion is as the square root of the pepsin concentration. The other method is the use of the centrifuge to hasten Hammerschlag's test, instead of waiting twenty-four hours for the precipitate to form by means of sedimentation. The authors were able to get accurate results in two hours. It must be recognized that the law of Borissow and Schütz is not applicable to concentrated solutions of pepsin, but only to those of moderate strength. The steps of the process are given as follows:

The gastric juice to be tested is diluted with three times its volume of a .2 per cent. solution of HCl. This diluted juice and the standard albumin solution are placed in the incubator about fifteen minutes in order to be warmed to body temperature. In each of two test tubes are placed 10 c.c. of the standard acidified albumin solution. To one tube 5 c.c. of the diluted gastric juice is added, to the other (the control tube) 5 c.c. of a .2 per cent. solution of HCl. These tubes are then placed in the incubator at 37 to 40 C. for exactly seventy minutes. At the end of that time they are removed, and 10 c.c. are taken from each tube and placed in the centrifugal tubes graduated to .02 c.c. To each tube is added 5 c.c. of a 10 per cent. solution of trichloracetic acid and, after inverting the tubes several times, they are placed in a high-speed centrifugal machine and centrifuged two hours. At the end of this time the tubes are removed and the volume of sediment measured. The sediment in the control tube will be an index of the original albumin strength of the standard solution. The sediment in the second tube will be less, if digestion has taken place, the difference in the two sediments representing the proportion of albumin which has been transformed into peptone.

21. **A Bread and Fruit Diet.**—Haig points out the advantages of a bread and fruit diet in the high-blood-pressure group of uric-acid food poisonings, which used to be considered special diseases under the names of epilepsy, neuralgia, asthma, Bright's disease, etc. The great point in the relief of these troubles is the lowering of the blood pressure which can not be brought about with a milk diet on account of the large proportion of fluid contained. By cutting down the fluid to the smallest amount compatible with comfort, and feeding on breadstuffs, dried fruit and fresh fruit, nuts, etc., a blood pressure of 150 to 160 mm. of mercury can be reduced, he says, in a week or two to one of 120, with a corresponding improvement in all the symptoms above mentioned. This diet not only reduces the blood pressure, but eliminates also the source of the uric-acid poisoning.

22. **Hallux Valgus.**—After noticing the various methods of operating for this condition, Sheldon gives his own as follows:

Once having removed the infected bursæ, the skin incision is made according to Dawbarn, except in cases with a tender bursa. In these cases excise the bursæ and as much of the overlying skin as is compatible with complete closure of the wound. The next step is to free the inner portion of the distal end of the first metatarsal with a chisel or periosteotome. The inner one-half or two-thirds of the head of the bone is then removed with bone forceps. The outer one-third or one-half of the articular surface of the metatarsal and the phalanx are not disturbed. The extensor tendons of the great toe are then divided. The fascia and ligaments are then drawn together with catgut and the skin approximated with silkworm gut. The toe is held in proper position with a planter splint and adhesive plaster. I usually apply a constrictor before operating; but, without constriction, the hemorrhage is slight.

He has operated on 12 cases in this way with invariably perfect results in three or four weeks. It assures a movable joint, there is no great toe shortening, and the deformity is corrected. If the bone is affected the abnormal part is removed; the space resulting from removal heals by the blood-clot process and the extensor tendons are so lengthened that they do not tend to reproduce the deformity.

26 *Caffein in the Treatment of Alcoholic Toxemia. Arthur J. Hall.
27 *A Case of Chronic Lymphatic Leukemia without Enlargement of the Lymph Nodes. George Blumer and Hermon C. Gordinier.

23. Speculative Investments for Physicians.—This article was written largely at the instance of Dr. Osler, who has noticed the constant attempts that are being made by promoters to induce physicians to become interested in speculative concerns. The general tone of the article is throughout discouraging to such investments. The successful speculator is the one who loses early and stops.

24. Thyroid and Parathyroid Bodies.—MacCallum notices the claim of Gontscharukow that he has produced a serum the use of which indicated the influence of specific antithyroid toxins and gives in detail his own experiments bearing on this point. He inoculated geese with thyroid extract and used their serum on dogs. On the whole his experiments throw doubt on Gontscharukow's results. As far as any results were obtained from his experiments, they were that an attempt to produce cytotoxins capable of destroying cells or glands *in situ* was a failure, but it may be possible that a material was produced in geese which, combined with the normal secretion of the dog's thyroid or parathyroid, might neutralize it and cause the symptoms that ordinarily follow extirpation to be mitigated in certain instances. He also experimented with parathyroid excision and remarks on the symptoms produced, which are somewhat similar to those of exophthalmic goiter. He concludes that it is probable that the parathyroid produces a material that neutralizes poison produced elsewhere and that the poison thus neutralized can be mechanically washed out with relief of the symptoms. He was able to relieve the symptoms produced by parathyroid excision by injecting the blood of a normal dog into the veins of a dog suffering from removal of these glands and the result was complete relief. He also experimented to determine whether the effects were on the roots of the motor nerves or higher, and concluded that it was not alone the neurons of the anterior horns, but the upper motor neurons were also affected. Urinary examinations were made and the results of all the experiments seemed to show that there was a distinct difference between the effect of the parathyroid and thyroid glands, the latter more or less controlling metabolism; the former having apparently an entirely different function. The question whether exophthalmic goiter is the result of thyroid insufficiency is unsettled, but he thinks it is doubtful that such is the case since we know that extirpation of the thyroid, including the parathyroid, relieves the condition in many cases. He has lately been treating a woman suffering from exophthalmic goiter with parathyroid, but so far without results.

25. The Skin Lesions of Rapid Growth.—Northrup describes and illustrates a case of lineæ albicantes of the knee occurring after typhoid fever in a rapidly growing youth, and quotes from Comby's work on children's diseases, the only one in which he has found a description of similar conditions.

26. Caffein in Alcoholic Toxemia.—Hall finds that caffein administered in doses of 1 to 2 grains every one, two or three hours will usually so effectually quench the thirst or craving for alcohol in twenty-four or forty-eight hours that most confirmed habitués will voluntarily discontinue its use. He reports four cases. Where there is insomnia due to the caffein, it is different from the insomnia of alcohol, and much less disagreeable. He does not advocate caffein as a specific, but it appears to be a physiologic antagonist to alcohol as much as belladonna is to opium. If this is once established, the contention that alcoholism is a disease will have to be abandoned, and the fact that it is a toxemia must be admitted.

27. Leukemia.—Blumer and Gordinier give carefully reported cases and discuss the pathology. They conclude that while myelogenic leukemia is invariably a disease of the bone marrow, lymphocytic leukemia may be a disease either of the lymph apparatus, the bone marrow, or of both. They further express the belief that specific differences exist between the blood picture of the different forms.

32 *Acute Lymphocytic Leukemia, with Reference to Its Myelogenous Origin. A. O. J. Kelly.
33 Primary Cancer of the Lung. J. H. Musser.
34 *Diabetes as a Complication of Pregnancy. Alfred Stengel.

32. Acute Lymphocytic Leukemia.—Kelly says our knowledge warrants the following opinions: The clinical manifestations and the blood pictures of leukemia justify the usual division into two clinical varieties, called the lymphatic and the myelogenous (or splenomedullary). Since, however, the so-called lymphatic leukemia may occur with little or no alteration in the lymph glands, and there is good evidence for believing that, whether these enlarge or not, the typical leukemic blood picture does not develop until the bone marrow becomes affected, the bone-marrow lesions appear to be the essential ones, and as both varieties of leukemia are myelogenous in origin, the terms lymphatic and myelogenous seem hardly appropriate. He prefers to distinguish the two classes as lymphocytic and myelocytic leukemia. There is no special line of demarcation between the two types, as transition forms occur. The disease, probably in all the cases, is the result of proliferation of bone marrow, but it is also likely that some of the circulating lymphocytes in lymphocytic leukemia are formed in the lymphoid structures elsewhere. The differences in the clinical course of the disease are probably attributable to differences in the chemotactic agent, whatever it may be, whether an infection or intoxication. He is inclined to attach much importance to the large mononuclear non-granular cells of the bone marrow in these cases, believing that it may form large lymphocytes or myelocytes, its development in one or the other direction being influenced by the nature of the chemotactic agent concerned. It is possible, too, that time has something to do with it; the basophile cells are looked on as the younger form, while the neutrophile cells and their derivatives are of the older growth. At present there is no way of distinguishing, when found in the blood, the lymphocyte derived from the lymph gland from that derived from bone-marrow, but it is probable that those found in the circulating blood in the healthy are derived entirely from the lymph glands, while those occurring in lymphocytic leukemia are derived in large part, and in some cases exclusively, from the bone marrow. Finally he remarks that the clinical manifestations of acute lymphocytic leukemia are especially of interest in their marked resemblance to typhoid fever. There is reason to think, he says, that some cases have been presumed to have been typhoid fever, and the error has not been rectified even at the necropsy. The differential diagnosis is by examination of the blood and by microscopic examination of the tissues.

34. Diabetes in Pregnancy.—The cases of diabetes developing during pregnancy are discussed by Stengel, who reports observations and refers to a number of histories by Matthews Duncan, who also tabulates reported cases. The most important question is that of prognosis. It is correct to assume it to be a condition of great gravity, but the seriousness of the condition has perhaps been overestimated. While the results for both mother and child are dangerous they are less frequently so than has been generally supposed and Stengel thinks that careful hygienic, dietetic and medicinal treatment should always be resorted to. Increasing glycosuria, diaceturia, grave weakness and rapidly increasing emaciation would, of course, suggest prompt intervention.

35 *A Few Reasons for Early Operation in Gallstone Disease. Park W. Willis.

36 A Philosophic Review of the Crowning Sin of Civilization. Ernest Crutcher.
37 Hypodermic Injection of Pilocarpin. R. W. Perry.
38 The Lumbricoid of the Tropics. J. S. Stott.
39 The Value of the Blood Examination. Robert M. Stith.

35. **Gallstone Disease.**—Willis reports cases and asserts that almost certain and permanent relief may be afforded by early operation with very slight risk to life and slight discomfort; otherwise there is liable to be serious trouble and possible malignancy. He questions the statement that the gall bladder has no function, and does not believe in cholecystectomy as a rule.

In the discussion following, Dr. Hutchinson held that the gall bladder was an entirely useless organ and practically obsolete, like the appendix, and should be removed whenever it causes trouble. He did not consider that gallstone was the cause of cancer, but vice versa.

42 *Displacement of the Uterus. Gustave A. Kletzsch.
43 Immunity and Its Relation to Surgical Pathology. J. M. Dodd.

42. **Uterine Displacements.**—Kletzsch says that every effort should be made to correct uterine malposition. If out of place, the general health of the patient must suffer sooner or later, but malposition alone is not the sole cause of this; the lacerated, subinvoluted and relaxed pelvic tissues contribute their part. We know, moreover, that retroversion or flexion is the first step toward prolapse, and neglect may make the conditions still more difficult to remedy. As regards operation, he says the ordinary Alexander operation ought only to be done in cases of pure displacements; if complicated by adhesions or procidentia uteri, this operation will fail. Vaginal fixation may bring the body of the uterus forward, but it destroys one of the main points of support, that is, to the base of the bladder and pelvic fascia, and this in time permits sagging downward. Fixation to the anterior abdominal wall may raise the uterus above the plane of the pelvis, below which it belongs, and also fix the fundus unnaturally, but to Kletzsch it is, nevertheless, the best operation for the great majority of cases. It must be supplemented by repair of any lacerations of the cervix or perineum, otherwise it will fail.

46 *The Deleterious Effects of the Excessive Use of Salt Chlorid of Sodium. (To be continued.) W. B. Parsons.
47 Hay Fever, Pollen Asthma, or Summer Catarrh. W. W. Woodring.
48 Relation of Orthopedics and Radiography. Byron C. Leavitt.

46. **Chlorid of Sodium.**—The experience of Parsons with chlorid of sodium has been rather peculiar. He had been an excessive salt eater, but at least eight years ago he began to have dizzy spells and hallucinations, also peculiar brain sensations and loss of memory. He had been a user of alcoholic liquors, sometimes enough to feel their effects, for twenty-five years. Thinking that this might be the cause he stopped, but without result. Then for a month he quit tobacco, which he had been chewing for many years, but with no change. Finally it occurred to him that salt might be the cause. He began to investigate, finding that salt in certain animal organisms was poisonous, and referring to his own clinical experience he found a case somewhat similar to his own. He therefore stopped the use of salt, with the result of the relief of all unpleasant symptoms, which again appeared on its re-use, hence he thinks salt was the cause of all his trouble. (His article is to be continued.)

September.

49 *Hayti—Klima und Krankheiten. A. Herzfeld.

49. **Hayti; Its Climate and Diseases.**—Herzfeld considers the climate of Hayti not unhealthy for the tropics. On the lower coast dirt and deteriorated civilization is the rule. He gives a black picture of the condition of the Haytian towns, but the minute one steps out of them one meets the most charming tropical vegetation. The diseases and climate are those of the tropics. After the European has been there for some months he generally suffers from the so-called local fever and then dysentery. The so-called "red dog," a sort of dermatitis caused by the sun is common, and he finds zinc stearate compound one of the best remedies. The habits of the sojourner there are generally bad as regards excesses. Cholera is not yet known; yellow fever occurs in epidemics; typhoid is not rare, and malaria in all its forms is frequent. Pneumonia and acute and chronic rheumatism are not rare in the coast region. Lepra and elephantiasis are frequent among the lower classes. Gonorrhea and syphilis are exceedingly common, and the blacks seem to be reckless and ignorant in regard to them. The drinking water is generally good and obtained through the old French aqueducts. The white population drink it mixed with rum "to kill the bacilli." The dwelling houses of the old Spanish style are good and are usually furnished abundantly with baths. The natives all take baths in a very primitive way, males and females together. He concludes by stating that Hayti is not yet afflicted with Eddyism and osteopathy.

50 *A Brief Résumé of the Literature on the Involvement of the Spinal Nerves and Cord in Influenza. Edward P. Carter.
51 *Cases of Isolated Paralysis of the Suprascapular Nerve. Frank E. Bunts.
52 Nephrectomy, Indication for, with Report of Five Cases. Henry A. Becker.
53 The Passage of an Open Safety-pin Through the Intestinal Canal. Hunter H. Powell.

50. **Influenza.**—Carter's résumé of the literature seems a fairly complete study of the subject. He concludes that under certain conditions the influenza toxin exhibits a remarkable predilection for the spinal nerves and cord, giving rise to a neuritis of the trunks of the peripheral nerves closely resembling that following diphtheria. In the spinal cord it is capable of reproducing almost any one of the pathologic conditions. As a rule, the involvement of the nerve trunks is very late, sometimes after the establishment of convalescence, and it is peculiar in not showing any affinity for any single nerve or group of nerves, but in being scattered. Recovery generally occurs rapidly after the subsidence of symptoms, though the case reported by Putnam and a number of instances by Franke appear as examples of chronic post-influenzal neuritis.

51. **Paralysis of the Suprascapular Nerve.**—Bunts has collected cases and discusses the etiology, pathology, etc. It seems to be due to sudden trauma or neuritis from other causes or associated with contusion or laceration of the nerve or loss of its continuity. The symptoms are summarized by him as: 1. Depression or shallowness of the supraspinous and infraspinous fossæ. 2. The impairment of external rotation of the arm. 3. Frequently a weakness in the elevation or abduction of the arm. 4. A probable slight displacement of the scapula. The diagnosis is not difficult, as a rule, but where it is obscure a few successive examinations, including electric reactions, will reveal the condition. It can not in all cases be made immediately; its rarity allows it sometimes to escape observation unless important symptoms are present. He thinks that cold and rest is the best treatment for cases due to sudden trauma, and suggests study of the synergistic action of other muscles that might be substituted for the paralyzed ones.

57 Report of a Typical Case of Exophthalmic Goiter. William H. Lyne.
58 Some Remarks on the Importance of Otorrhea. Clifton M. Miller.

55. **Pulse Tension.**—The importance of pulse tension in obscure brain lesions, comatose conditions, typhoid, pneumonia, etc., are noted by Cook, who mentions the remedies that are

applicable. Of the cardiovascular stimulants, strychnin is undoubtedly the most reliable. Digitalis should be used with caution; it is valuable in toxic conditions. Cocain is useful, but transitory in effect. Adrenalin can hardly be regarded, he thinks, as either a cardiac or a vasomotor stimulant. He believes it distinctly injurious to the muscle fibers of the heart. The 3 cases which he saw die under its continued administration all closed with symptoms of cardiac poisoning, and he believes that, while it kept the patient alive for hours in shock, the drug was responsible for the ultimate cardiac failure. Aside from its local administration to stop hemorrhage, the uses of adrenalin are limited. Its administration as an arterial stimulant should be confined to desperate cases of profound shock where low tension pulse threatens immediate dissolution. Alcohol he never found to have any true stimulant action on the pulse tension. Saline infusions are likewise wanting in any true stimulant action. They are invaluable in aiding elimination and helping to refill the depleted vessels. Of the depressant drugs amyl nitrite acts promptly, but is very transient. Nitroglycerin acts in a few minutes, causing a fall which can not be recovered from in less than an hour. Sodium nitrite acts more slowly and is better for continued administration. In conclusion he mentions two conditions where the use of the accurate estimation of the pulse tension has been found valuable: 1. In following changes in patient's condition during anesthesia and operative manipulations, especially where the condition is weak or dangerous, and during chloroform anesthesia, which has a marked depressant action. 2. In detecting perforation in typhoid, daily routine estimations of blood pressure afford a new basis for decision. A sudden rise in blood pressure, in connection with suspicious symptoms, is strong confirmatory evidence. An unchanged blood pressure in spite of suspicious symptoms almost excludes the possibility of perforation.

59-62. Variola.—The articles on variola, etc., have already been briefly referred to editorially.

65. The Digestion of Tissues.—Levene and Stookey have studied on three lines of research and here give their conclusions and the methods of analysis. They used an extract of fresh pancreas or other tissue and the white of an egg, boiled and unboiled. Unboiled extracts are digested more slowly than the ones that have been heated. The strength of the digestion depends on the quantity of enzyme added. The action of certain small quantities of pancreatic extract may be almost inhibited by unheated white of egg, though effective when added to previously heated egg white. It is evident, they say, from their experiments that in the course of digestion the enzyme action and the inhibitory action of the tissue extract become gradually exhausted. As regards the second point studied, namely, whether the tissue extracts inhibit proteolytic enzymes, it appears probable that the inhibitory action of the neutral extract is destroyed by acetic acid in the extract of spleen and liver, and that the acid extract contains their enzymes. In pancreatic extract and in the white of the egg an inhibitory action against the intracellular enzymes is demonstrated. The third question was whether the inhibitory action of the blood and tissues can be increased by immunization. The experiments showed that the blood of the immunized rabbits offers a markedly higher resistance toward tryptic digestion than that of the normal animal, while the behavior of the same blood toward splenic and hepatic extracts was not much different from that of normal blood. This may have been due to the fact that the inhibitory power against the enzyme was destroyed by the acetic acid. The work on immunization of animals against enzymes of the liver and spleen is in progress.

69. Diabetes.—From the experiments here detailed as to the recognition of blood in diabetes mellitus, Sweet considers the following conclusions justified:

1. The subcutaneous injection of an alcoholic solution of phloridzin, which causes a transitory glycosuria, is showed by a slight, though readily demonstrable, increase in the serum of the rabbit of the hemolytic complement for bovine erythrocytes; this increase is to be explained as occurring coincidently with the inflammatory reaction of the organism to the injection. 2. No effect of injections of phloridzin on the amboceptor for bovine erythrocytes can be demonstrated. 3. The intraperitoneal injection of adrenalin chlorid is followed by no marked effect on the blood reactions; the injection may, however, cause an inflammatory reaction, and so cause an increase of complementary activity. 4. The complete removal of the pancreas from dogs, which causes a true diabetes mellitus of severe type, is followed by a marked decrease of the hemolytic activity of the diabetic dog's serum for both rabbits' and guinea-pigs' erythrocytes. 5. The diabetes caused by the complete extirpation of the pancreas is further characterized by what is to be interpreted as a complete loss of the normal bactericidal property of the serum of the dog. . . . 6. This decrease of the hemolytic activity of the diabetic dog's serum for is due to loss of hemolytic complements. . . . 7. The complete removal of the pancreas is as necessary to this loss of complements as it is to the production of a diabetes. 8. The complete removal of the pancreas has not deprived the organism of its power to react to the inflammatory process by an increase of the complementary substances. 9. No disturbance of the normal relation of the receptors of the erythrocytes to specific hemolytic amboceptors can be demonstrated in the course of a true experimental diabetes. 10. The loss of the complementary substances in diabetes mellitus points conclusively to the fact that no relation exists between the leucocytes of any type and the production of the complements. 11. A decrease in the amount of glucose excreted by the diabetic organism can not be shown to occur in the course of a secondary infection, at least during the earlier stages of the diabetes.

75 Iliac Abscess—Operation and Treatment. A. F. Stewart.

71. Mineral Waters in Indiana.—Kahlo describes the mineral springs in Indiana and their merits. Winona, in Kosciusko County, possesses a mild alkaline-calcic water of merit in gastric disorders, incipient nephritis, renal calculi and cystitis, which contains 15.54 grains of calcium bicarbonate with 8.48 grains magnesium bicarb. per gallon. Mudlavia possesses a similar water, but is chiefly famous for its mud baths. The most popular resorts in Indiana are French Lick and West Baden Springs, which are practically one place, only a mile apart, and have excellent facilities for accommodating patients. The waters there are sulpho-saline-alkaline, containing 347 gr. of solids to the gallon, chiefly calcium, magnesium and sodium sulphate, magnesium carbonate and sodium chlorid, with traces of other constituents and carbonic acid in the proportion of 433 parts per million. He recommends these baths for chronic gastritis with deficient secretion and excessive mucus, associated constipation and disturbed metabolism; also in the irregular type of gout and in lithemia they seem to act as a specific. They are also useful in cholelithiasis, hepatic congestion and the early stages of cirrhosis. In albuminuria and diabetes he has seen the disappearance of the abnormal urinary constituents after a few days' treatment, but was not able to follow any of these cases beyond their stay at the springs, and can not, therefore, speak as to the permanent results. Advanced cases of nephritis were seemingly aggravated. Hyperchlorhydria and pregnancy are other contraindications. Cystitis, urethral inflammation, rheumatism and certain chronic cutaneous diseases are also benefited, the latter probably in part the result of external employment of the waters. There is apparently very little ac-

quired tolerance of the effects of these waters in constipation, and the relief is generally more or less permanent. He speaks of the effect of change of scene and adds a word of warning regarding the tendency to drink the stronger waters too frequently, especially if near meals.

72. **Tuberculosis Among the Insane.**—White pleads for the isolation of the tuberculous insane, as it is impossible, he thinks, to make them observe the ordinary precautions which would make their association with other patients safe. He would advise that each patient on admission be accompanied by a statement of the examining physician, including the family history and existing physical condition as regards tuberculosis, so as not to misplace cases on their reception. The sputum examination and tuberculin test are both recommended as diagnostic aids. The serum tests, he thinks, will be of service when better perfected.

76. **X-Rays in Diabetes.**—Comstock warns against the use of the *x*-rays in diabetes, especially when the part treated is in the foot or hands. He reports a case in which the reaction of the tissues to the rays was so much out of proportion to what was expected that it was hard to explain the patient's susceptibility excepting on the ground of weakened tissue due to diabetes. Hence, he thinks, the need of this caution. The bad results were not permanent.

82 *Prostatectomy; Its Indications and Technic. G. Frank Lydston.

81. **Adrenalin in Dentistry.**—Menger has tested the combined action of adrenalin and cocain in the extraction of twelve teeth at one sitting. The results were so satisfactory that he reports the case. The immediate and after-effects were more effective and pleasant than under chloroform narcosis. The injections had to be continued during the operation, but there were positively no bad after-effects, notwithstanding the extreme nervousness of the patient. A 5 per cent. cocain solution and one-half part of 1 to 1000 adrenalin solution, injected along the alveoli, was used.

82. **Prostatectomy.**—Lydston reviews the indications and methods of prostatectomy. He thinks the Bottini operation should be considered only as a late resort in such cases, and has very narrow limitations. It is useful only when rational surgery is not applicable, and should be considered an operation of necessity rather than election. He prefers the perineal method, but employs the suprapubic section if necessary. No single operation can be successfully used in a routine way. He remarks that he has several cases under observation in which a suprapubic fistula has been made, and the patients are so well satisfied that they will not listen to any suggestion of radical operation.

2. **Erb-Duchenne Paralysis.**—Harris and Low report and discuss three cases and conclude that the fifth cervical is chiefly involved. A study of the articles of Thornburn and Sherrington and a remarkable case of Markoe seem to prove that motor innervation of the deltoid, spinati, biceps and brachialis anticus is derived from the fifth cervical root and they, therefore, operated, uniting this root to the sixth. In no case has the time elapsed been sufficient to judge as to the perfect success, but the results thus far seem promising. The operation, while it has some difficulties, is not an impracticable one, and is worth trying. There will have to be some relearning of the muscles and co-ordination of impulses with the new connection, but the authors say in all probability the nearer the two nerves are to one another in respect to the cord segment to which they belong the less the difficulty will be after cross-suturing in overcoming any tendency to inco-ordination. They, therefore, recommend suturing the fifth root into the sixth rather than into the seventh in such cases, as they consider that the sixth is not affected in the ordinary form of this paralysis. They also specially urge the importance of employing careful faradic stimulation of the nerve trunks in all such operations as an aid to accurate scientific diagnosis.

4. **Gastric Ulcer.**—Griffiths treats all his cases of gastric peptic ulcer by putting the stomach absolutely at rest and abundant rectal feeding. The patient is put to bed for at least twelve days, the bowels cleaned out by enemata and rectal feeding commenced almost immediately. Nutrient enemata at a temperature of 97 to 100 are given every four hours and in the intervals drink enemata given according to the needs. He does not allow the patient to take any liquid by the mouth, and the stomach should be kept absolutely quiet. He specially mentions the condition of the tongue and the smell of the breath as valuable guides to the efficiency and sufficiency of the rectal feeding. When it is sufficient the tongue is moist and healthy, and the breath is sweet, while that of a starved patient has a peculiar offensive smell, which is hard to describe; perhaps the closest to it is the drunkard's breath. Moreover, the patient is comfortable when sufficiently fed. When the rectum is intolerant of an artificial enema, which rarely occurs, he would give a few minims of laudanum, 5 to 10 minims, two or three times in the twenty-four hours. Feeding by the mouth is very carefully begun on the eleventh day.

Rolleston follows much the same lines, forbidding all water or any food by the mouth and relies on rectal injections entirely. As regards medicinal treatment he would try potassium iodid in chronic gastric ulcer of adult males, as there is a possibility of specific character. The importance of local treatment of the mouth can not be overestimated. Carefully washing out the stomach with mild antiseptic solution or water or the running in of a large amount of bismuth are sometimes usefully employed. Of course the symptomatic treatment of the patient is sometimes required. Parotitis, which is a complication occasionally seen in gastric ulcer with rectal feeding, rarely requires operation. Apart from perforation the only acute complication which requires operation in gastric ulcer is repeated hemorrhage, which does not yield to medical treatment and endangers life. He speaks of the importance of oral sepsis in producing vomiting. He has seen striking benefit from counter-irritation by blisters to the epigastrium. In chronic gastric ulcer operation is justified when there is constant pain not relieved and when there is an intermittent or permanent pyloric obstruction and lastly, when hematemesis recurs in spite of the medical treatment.

6. **Tuberculosis.**—Chowry-Muthu reports the results of treatment of pulmonary tuberculosis by the inhalation of formaldehyd or creosote vapor in connection with the open-air treatment. Notwithstanding the use of the latter, he thinks the drug treatment had its effects. He has also tried intravenous injection and considers it also of value. He speaks well of the electric treatment on the Crotte plan. The open-air treatment, he says, requires a great sacrifice of time and means, and should be supplemented by something else. Serum-therapy is in its infancy. Special drugs by the mouth are disappointing. Tuberculin has not yet developed. The continued inhalation and vapor treatment by formaldehyd is simple and can be used in all cases. The intravenous injection used with gas should be given a trial in the early cases, and if it does no good it at least does no harm. The electric treatment is plausible and hopeful.

8. **Tuberculosis.**—The comparative value of oral and rectal temperatures of pulmonary tuberculosis is discussed by Kelynack and Williams, whose conclusions are as follows:

1. Temperatures carefully taken in the mouth during rest form a reliable guide in the management of phthisical cases under conditions of sanatorium life. 2. Temperatures taken in the mouth during or shortly after exercise can not be considered trustworthy unless registered with such precautions as militate against their general practical applicability. 3. Temperatures taken in the rectum during rest, generally speaking, register higher than in the mouth, but do not otherwise usually afford any special assistance in the management of phthisical cases. 4. Temperatures taken in the rectum during or shortly after exercises, in both healthy and phthisical subjects, register a temperature considerably higher than that in the mouth and, while in the non-tuberculous the return to normal is more rapid than in the tuberculous, no special direct advantage for the phthisical appears specially to accrue from this method. 5. For practical purposes in the management of phthisical cases undergoing so-called sanatorium treatment the registration of temperature by the oral method, when taken during rest and with due care, affords reliable guidance.

12. **Muscle Testing.**—Hedley calls attention to the degenerative reaction as an important diagnostic aid. He thinks that with all the new things, the medical man is in danger of forgetting older valuable methods. The practical clinical point he makes is that while increased anodic contraction with decreased cathodic contraction—which is given as an essential point in the recognition of degeneration by some—is an important

symptom of degeneration, we must not expect it to be always present as its appearance depends on the realization of many conditions.

21 On the Value of Saline Infusion in the Treatment of Enteric Fever. D. G. Marshall.
22 The Value of Blood Examinations in Abdominal Diseases. C. J. Nepean Longridge.

17. Colon Perforation.—Bland-Sutton reports and illustrates two cases which show that a foreign body may perforate the large intestine and lodge in an epiploic appendix. The bodies in these cases were pieces of straw and metal. These foreign bodies are enclosed in fecal concretions which show how angular and dangerously pointed bodies may traverse the colon and be safely ejected without harm to the host. Common as anal abscess is, he thinks it stands in very small proportion to the number of cases where small foreign bodies are daily ingested and ejected.

19. Carbolic Acid in Smallpox.—Brindley and Bonis report the results of cases in which smallpox was treated by penciling the vesicles with pure carbolic acid. The effect was shown in the rapid shriveling up and scabbing of the vesicles. Two or three applications may be made if necessary over certain parts of the body. An important part of the treatment is the securing of early removal of scabs by oil poultices or otherwise to prevent subsequent abscess formation. The action of the drug is not irritating, but rather palliative, and appears to be a local one, the acid penetrating the walls of the vesicles and disinfecting their contents. The total number of cases thus treated was 35, of which 22 were of the severe kind, mostly confluent; 5 were fatal, 2 of these were complicated with scarlet fever, and a third was malignant smallpox with subcutaneous hemorrhages. A large number of the cases had never been vaccinated.

20. Intestinal Anastomosis.—The method here described by McLennan consists in a curved, slightly tapering bone bobbin, the narrow end of which is inserted into the proximal end of the gut. It is fixed there by a ligature which binds the intestine into the outermost groove (A). Over this ligature is placed a plain rubber ring similar to an umbrella ring, which must be tight, but not too tight to prevent its being easily placed in position. The proximal end of the intestine so armed is inserted into the distal end of the gut far enough for it to cover the second groove (B). The distal end is ligatured into this groove over the proximal end in a manner similar to that by which the proximal end is fixed to the bobbin. The rubber ring under the distal end of the bobbin then has to be gently manipulated backward from its resting place over the first ligature in groove A and past groove B, lodging at last into the most inner groove (C). The conical shape of the bobbin favors this manipulation. Care must be taken that it is not pushed beyond groove C. Union is then completed by stitching the cut borders of the mesentery. Eventually all distal to the rubber ring comes away. The operation is an easy one to perform and takes much less time to carry out than to describe.

25 *Entrance of Air Into Veins During Gynecologic Operations. X. Delore.—De l'entrée de l'air dans les veines pendant les opérations gynécologiques.

23. Pearlworkers' Osteomyelitis.—Ignorance of the subject's trade may lead to an erroneous diagnosis, as this affection may simulate a tuberculous osteitis or subacute osteomyelitis. The surgical treatment necessary for the latter is useless, if not injurious, in pearlworkers' osteomyelitis, which subsides promptly on removal of the cause with complete return of the functions of the parts. In a case described in detail—the first in France—removal of the cause, with rest, was all the treatment Broca attempted, and recovery was complete in two months. The affection appears about the time of puberty, and is characterized by a hard, painful tumefaction of one or more bones of the limbs or face, gradually extending. It develops in the course of a few weeks or months, with slight general symptoms, and then subsides spontaneously, but displays a tendency to recurrence.

24. Splenectomy in Banti's Disease.—Quénu and Duval had a patient with splenomegalia and cirrhosis of the liver under observation for a long time, but the symptoms were bearable. Another patient exhibiting the same but severer symptoms was treated by extirpation of the spleen. Comparison of the course of the two almost identical cases shows the great benefit derived from the operation, the first of its kind in France. The spleen showed excessive development of some of the veinules and capillaries, with sclerosis of the trabecular tissue and atrophy or, at certain parts, actual disappearance of the malpighian corpuscles. In this case and in 3 reported by Banti, in which the cirrhosis of the liver had been clinically recognized, all treated by removal of the spleen, the patients were all restored to health except one, who succumbed to puerperal septicemia. There was no postoperative hemorrhage in any instance, and one of the subjects who had had hematemesis before was not troubled in this way afterward. The liver affection seems to retrogress, or at least be arrested, after the splenectomy, evidently due to the removal of the cause. Bessel-Hagen advocates splenectomy at any stage of the disease, but Quénu would restrict it to cases in which the patient was incommoded by the size of the spleen. Until this occurs he would not venture to remove it on theoretic grounds alone, and therefore refrained from intervention on his first patient. The patient operated on has recovered complete health, has married and borne two healthy children. The recovery was equally pronounced and permanent in Banti's cases treated by splenectomy, and, on the other hand, there is not a single case on record of recovery of a patient not operated on. Removal of the spleen is an empiric procedure, but experience shows that it cures the disease. The same result may possibly be secured by combining omentopexy and splenopexy, as suggested by Schani, but this has not yet been tried in the clinic.

25. Entrance of Air into the Veins During Operations.—Delore has been studying this subject since he witnessed the death of a woman from this cause during an abdominal, subtotal hysterectomy. He reviews the history of what is known in regard to the effects of air in the veins, both in experimental research and in the clinic. The fact is well established that sudden entrance of air into the veins is liable to prove fatal, and that dilatation of the veins is a predisposing factor. Another important factor is extreme anemia, noted in the case described and also in one reported by Biermer under the title of gaseous embolism during enucleation of a uterine myoma. The air replaces the lacking blood in the veins. It is possible, likewise, that the Trendelenburg position may have favored the introduction of air in the 2 cases mentioned. Thoracic aspiration is undoubtedly the cause of the entrance of air, and it might possibly be prevented by preliminary hemostasis in cases of pronounced anemia. Section of the vein between two forceps not only prevents hemorrhage but also entrance of air. When the air has entered, the opening in the vein should be closed at once to prevent further influx. Bégouin's experiences with animals are instructive. After insufflating air into the jugular vein of rabbits and dogs, he introduced a Dieulafoy aspirator into the right ventricle. As the air escaped the animal resumed the appearance of health while all the controls were rapidly dying. Insufflating more air later again into the vein after recovery, without subsequent aspiration, was followed by the almost immediate death of the animal. The results of these experiences

have not been applied to man, but puncture of the right ventricle might be advisable as a last resort in case of sudden penetration of air into the veins entailing distention of the right heart and alarming symptoms. When the air enters more gradually, even a much larger amount may be tolerated by the subject without much disturbance and with ultimate recovery.

26. Diagnostic Significance of the Color of the Cerebrospinal Fluid.—Bard has long been expatiating on the importance of the information to be derived from his "three-tube test" examination of the tint of the centrifugalized fluid derived by lumbar puncture. Out of 300 cases in which lumbar puncture was made, the fluid showed an abnormal tint in 20. Besides the tint it is possible to examine the cytology of the fluid, the permeability of the meninges to iodid of potassium from without inward, and the variations in the hemolytic power of the fluid. In regard to the cytology, only the finding of desquamated endothelial cells has much diagnostic value. The permeability of the meninges to potassium iodid, previously ingested, may be useful, perhaps, in case of a non-hemorrhagic fluid, but in case of blood it does not convey any information as to whether the blood entered by transudation or by irruption. The variations in the hemolytic power of the cerebrospinal fluid are valuable indices, as under normal conditions the fluid does not dissolve the reds of the subject except at a dilution of 12 drops of distilled water to 10 drops of the fluid. In case of meningeal hemorrhage this power is augmented, and 4 to 6 drops of distilled water produce the same effect as the 12 drops in normal conditions. High hemolytic power is therefore a sign of a hemorrhagic lesion, while the reverse indicates an accidental hemorrhage. When the centrifugalized fluid exhibits a yellowish tint not due to hemoglobin, it is probably due to a pigment derived from hemoglobin left from old hemorrhagic exudations.

39 (Supplementary No.) Report of Czerny's Clinic, Heidelberg, for 1902.

31. Fracture of Upper Arm Above the Condyle.—Hilgenreiner emphasizes the necessity for differentiating between fracture from extension and fracture from flexion, as they require opposite treatment. He recommends early massage, and as soon as consolidation has occurred, tepid baths and active movements. He has observed 21 cases and describes them, with 30 radiographs and a review of the literature. Two-thirds of the cases occur between the fifth and tenth year.

33. Operation for Hydrocele.—Suzuki reports 33 cases operated on by Winkelmann's technic. In the majority the suture could be removed the fifth to the eighth day, and the patient could be dismissed the eighth to the tenth day. The operation was done with Schleich's anesthesia in most instances. Out of a total of 137 cases on record to date, recurrence has been noted in only 6. The method seems to be preferable to all others, as the intervention is insignificant, the healing is more rapidly completed, general narcosis is not necessary and the subject can be treated as an out-patient.

34. Remote Results After Gallstone Operations.—Schott reviews the experiences at Heidelberg with 180 patients operated on for gallstones. A later series of 170 cases is not included in this summary. In 11 per cent. stones were discovered later; in 8 per cent. emerging through the fistula. There was recurrence of pains in 1 per cent., with icterus in 10 per cent. of the conservative operations and in 15 per cent. of the drained cases. Bile fistulæ occurred in only 4.4 per cent., while in previous years the proportion was 9.1 per cent. Czerny ascribes this better result to his present practice of fastening the gall bladder to the parietal peritoneum and inserting a drain tube to which the edges of the wound cling so closely that the mucosa of the gall bladder does not project into the abdominal wound, interfering with its healing. Gastro-intestinal disturbances were noted in 36.6 per cent., probably due to formation of adhesions. In the total 180 cases followed for from five to six years there has been permanent cure of the tendency to biliary lithiasis in 95 per cent. Genuine recurrence of stones was not observed in a single instance, and in only 5 per cent. have symptoms developed which could possibly be attributed to the biliary system. The mortality of gallstone operations has been reduced to 5 per cent. and of cystostomy to 1.3 per cent. Cystectomy shows only 20 per cent. mortality and choledochotomy only 4.4 per cent., in comparison to the 12 per cent. of former series operated on. These percentages justify early operating in case of gallstones.

35. Surgery of Gastric Cancer at Zurich.—Schönholzer continues his review of Krönlein's operations. In this part he gives the details of 55 cases of gastrectomy with 27.2 per cent. mortality, and of 91 gastro-enterostomies, with 23 per cent. mortality.

37. Actinomycosis at the Tuebingen Clinic.—Heinzelmann reports 56 cases operated on since 1885. The prognosis depends on the localization of the process permitting extirpation. Of 39 cases in which the face was affected 98.7 per cent. were permanently cured. Of the 11 cases of abdominal actinomycosis, 27.2 per cent. were cured. Potassium iodid is always given in addition to the operative intervention.

42. Operation for Inguinal Hernia.—Hofmann remarks that in incipient inguinal hernia he has always been impressed with the large size of the internal ring, evidently congenital. He has also noticed that the spermatic cord seems to separate into its parts toward the back of the inguinal canal, and the hernia may find its way through between them, instead of merely pushing the cord—as a whole—to one side. He thinks it important not to touch the tissues with the fingers, and to open up the entire hernial sac and internal inguinal ring. The sac is then dissected out from the rear forward, carefully refraining from disturbing the funiculus spermaticus, leaving it unmolested in its nest. The operation then proceeds as usual, laying the main stress on the obliteration of the sac at the level of the parietal peritoneum and providing a support for it at the internal inguinal ring with one or more sutures of wire. The normal anatomic relations are carefully regarded and reproduced, the spermatic cord not removed from its place. He applies the supporting suture by passing the wire or other material through the internal oblique, then through the transverse fascia of the posterior wall of the inguinal canal, passing between the separate parts of the spermatic cord, and finally through the everted Poupart ligament. Tying the ends of the suture closes completely the inguinal canal without injuring the parts of the spermatic cord. The closure is more complete than with a Bassini.

A year has passed since he first began using this technic, and the results have been perfect to date.

43. **Combination of Rubber and Thread Gloves.**—The advocates of rubber gloves and of thread gloves are informed by Goepel that the advantages of both, with none of the drawbacks of either, are combined by simply drawing a pair of thread gloves over a pair of rubber gloves.

50. **Emergency Strumectomy During Pregnancy.**—Fellenberg was called in 2 cases to relieve women suddenly suffocating from compression of the trachea by a goiter. The trachea was flattened to such an extent that tracheotomy alone would have been useless. After making an incision from the sternum to the cricoid cartilage, he carried it to the left in a Kocher angular incision and pushed out the incarcerated lobe, thus removing the pressure from the trachea. Artificial respiration was then applied and the patient revived, after which the remainder of the gland was extirpated at leisure. Although there had been no opportunity for disinfecting the field, the wounds soon healed. One woman bore a viable child two days later and the other healthy twins a month afterward.

52. **Obstetrical Bag.**—The points on which de Seigneux lays most stress include the keeping of each instrument wrapped in a separate linen bag, and placing all the instruments needed for certain interventions together, wrapping the group in a cloth fastened with safety pins. The entire bundle is then boiled; all danger of rusting is prevented by addition of a 20 gm. tablet of borax to the liter of water.

53. **Determination of Blood in Stools and Vomit.**—Rossel has devised a method of blood determination which has never failed him. It revealed blood in the stools in suspicious cases of ulcus ventriculi when it was impossible to detect it by other means, and even the spectroscope findings were negative. The results of the test were confirmed by the course of the affection. The reagent is a mixture of an aqueous solution of Barbadoes aloin, alcohol and turpentine. In testing cases in which cancer or ulcer is suspected, the subjects must refrain from previous ingestion of meats, etc., containing blood and from iron medication.

54. **Favus in Man and Animals.**—Wandel believes in the multiplicity of favus, his researches indicating that the favus of mice is sometimes transmitted to man, but that the latter has an individual favus. A third variety, which mostly affects dogs, is scarcely ever transmitted to man. Fowls have still another kind of favus.

55. **Excessive Ascites from Thrombosis of Portal Vein.**—The liver was small but the biliary secretion was normal in the case described. The peritoneum absorbed the ascites in large measure, and the amount of the fluid poured out daily into the abdominal cavity could be increased by giving a diet poor in albumin, and diminished by giving abundance of albumin, especially milk. The proportion of nitrogen in the ascitic fluid varied with the amount of nitrogenous food taken, and nitrogenized extractives were found in it. By diminishing the intake of fluids the excessive transudation could be somewhat modified and the time for the next puncture postponed a little. About 20 to 25 liters were withdrawn at each puncture. There was nothing to explain the origin of the thrombosis in the portal vein.

56. **Visceral Syphilis.**—Among the interesting cases described by Quincke is one in which gummatous indurations in the cystic duct and head of the pancreas could be palpated in a syphilitic subject, with typical attacks of gallstone colic, which were assumed to mean a superposed biliary lithiasis. An operation, however, disclosed that there was no tendency to gallstone formation, but a tumor was found which was not disturbed. It subsided under iodid treatment. In a second similar case the portal vein and biliary passages were compressed by a gummatous proliferation. In a third, a gumma in the mesentery had caused stagnation of stomach contents and dilatation of the organ. The gumma was nearly as large as a man's fist and had developed to this size in the course of six weeks in an old syphilitic. Measures directed against the stomach conditions proved ineffectual, but under mercurial inunctions and iodid there was marked improvement. He also reviews a number of cases of aneurisms in syphilitics and 3 of brain syphilis. One of the latter patients presented a permanently subnormal temperature.

57. **Study of the Oxyuris.**—Heller describes the development of these parasites and the best mode of expelling them. The eggs passing from the mouth into the stomach hatch there and the embryo then travels into the small intestine. The female travels through the cecal valve and lays her eggs on the feces or mucus in the large intestine. The life cycle from the egg to sexual maturity is about five weeks. The best mode of expelling the parasite is to attack the young brood in the small intestine by administering calomel. This seems to be particularly effectual in carrying away the intestinal mucus which protects the parasites against the action of the vermifuge. Santonin or something of the kind is then given and followed by another purgative. This expels the young; the females in the large intestine can be evacuated afterward by an injection of one to three quarts of a .2 to .5 per cent. solution of sapo medicatus, taken in the knee-elbow position. This course of treatment should be repeated in a week, and the subject instructed to avoid reinfection through the dirt under the fingernails, etc.

58. **Pathologic Anatomy of Tetany.**—Peters announces that the histologic study of 8 cases of tetany has revealed that it is an organic affection, the lesion consisting in an interstitial neuritis or ganglitis. The part affected is the extradural connective tissue, and the lesion is a small-celled infiltration with hemorrhages or fibrinous deposits, or a jelly-like infiltration into the epidural tissue. This interstitial neuritis affects both motor and sensory nerves in their extradural portion. The intradural and intramedullary portions are free from it, and also the peripheral nerves. The ganglitis may assume the form of proliferation of the intracapsular endothelium or of infiltration of round cells into the stroma of the ganglion, or of degeneration of the protoplasm of the nerve cells with karyolysis. The process involves the nerve roots innervating the parts that are the seat of the muscular spasms. The latter

are not merely root symptoms from inflammatory irritation of the motor nerves, but are principally due to this pachymeningitic inflammation in the sensory sphere and exaggerated excitability of the motor nerves. This overexcitability of the motor nerves is the result of mechanical compression of the motor fibers in the root region by the products of the inflammation. As the openings in the dura and between the vertebræ are about of a constant size, the effect of these local pathologic processes is most marked the larger the size of the emerging nerve roots with their vessels. As the seventh and eighth cervical roots and the lowest lumbar and upper sacral roots are the thickest, the parts innervated by these roots suffer most from the effects of the lesions. Trousseau's sign can likewise be explained by this compression of the roots and vascular congestion with the entailed overexcitability of the nerves involved. Peters adds that he has noticed a new phenomenon characteristic of tetany, constant in 78 cases examined. He calls it the "jumping-jack sign." If the anode of a current of 3 to 4 milliamperes is placed on the breast, the cathode on the spine near the fifth to seventh cervical vertebræ, the arms jerk like those of a jumping-jack when the string is pulled. The legs jerk in the same way if the electricity is applied lower down, and on one side alone if applied to one side of the median line. This jerking is evidently due to overexcitability of the nerve roots.

59. **Disturbances in Circulation in Infectious Diseases.**—Pässler and Rolly state that their experimental and clinical researches have shown that the disturbances in the circulation induced in the course of acute infectious diseases are due to vasomotor paralysis. This is compensated for a time by extra work on the part of the heart, but the heart soon suffers from lack of its usual blood supply and becomes unequal to the task. The collapse is thus due not to direct injury of the organ by the infection but to the inadequate blood supply in consequence of the vasomotor paralysis. If it is possible to restore the blood supply of the heart approximately to normal, then it resumes its work and collapse is averted. In case of diphtheria, the heart may suffer in time from the direct action of the diphtheria toxin, its resisting power being reduced under the influence of the toxin until it may finally yield even without primary vasomotor paralysis. Pneumococcus toxin does not have this injurious effect.

74 *Does Hygiene Lead to Race Degeneration? Max Gruber.—Führt die Hygiene zur Entartung der Rasse? (Commenced in No. 40.)

63. **Acute Infection of the Cecum.**—Reisinger reports two cases of apparently primary gangrenous typhlitis, in one of which constipation played an important part. In both cases the cecum alone was involved and the appendix was normal. He discusses the pathology of these cases and suggests that the peritoneal, free portion of the hinder cecal wall is less resistant than other parts, hence the danger of gangrene. He thinks the rule should be in deep-seated stenosis of the large intestine, where an artificial anus is required, that the cecum be examined and further treatment regulated by the findings. If there is danger from the cecum it would be better to make the artificial anus at this point rather than at the sigmoid flexure.

64. **Bacteriuria.**—Cnopf reports cases of children in which an infectious fever existed at first of dubious diagnosis, but which was explained by the examination of the urine, showing infection with the colon bacillus or with other microbes. He holds that infection of the contents of the bladder may occur without irritation of the bladder wall, and produce general symptoms with which the subjective symptoms do not altogether harmonize. In order to avoid confusion it is necessary not only to examine the urine chemically, but also bacteriologically, to get a fair idea of the nature of the disease and also the possibilities of its treatment.

66. **Epidemic Pneumonia.**—A suddenly-occurring epidemic of croupous pneumonia in a small German village is reported and the probable causes discussed by Spaet. He concludes that the spread of the disease, involving as it did some 13 per cent. of the population, must have been by contagion. Pneumonia undoubtedly is a contagious disease, but the contagion seems to depend more or less on local and temporary conditions, which need further study.

67. **Lung Abscess.**—Karewski holds that while natural healing of acute cases may occur in young individuals, and in case of small foci lying in the lung apices or larger ones in the base of the lungs, unless one sees that spontaneous opening is decidedly probable, or if the abscess does not completely empty itself, it is desirable to resort to operation. Before everything else, the condition of chronic suppuration must be avoided and timely operation prevent the formation of multiple suppurative foci.

69. **Hypoesthesia in Appendicitis.**—A number of cases are reported by Peiser. Nine of them showed marked abnormalities of sensibility in the right lower abdominal region. In one it was not certain, and in another there was no disturbance. Of the 9 cases noted, hypoesthesia existed in 6, and in 2 hyperesthesia, and 1 began with lessened, but ended with increased, sensibility. The local sensory disturbances were not well defined, and Peiser was not able to fully follow up the investigation. He asks, however, certain questions as worthy of note in regard to the occurrence of diminished sensibility in appendicitis: 1. In what percentage of cases of appendicitis do we find disturbance of sensation and what proportion of hypoesthesia and hyperesthesia? 2. What common symptoms have the cases of each kind? 3. Is there a difference as regards the intraperitoneal and retroperitoneal position of the appendix? 4. Have suppurative pus collections (greater or lesser) any influence on the occurrence and form of sensory disturbances? 5. What is the relation of this disturbance to the clinical course of the appendicitis before and after operation? 6. Does the number of preceding attacks have any influence on the course or form of the disturbance? 7. What is the condition as regards sensory disturbance in persons who have gone through an attack of appendicitis, but for the time are free from the disorder? 8. How are the sensory disturbances to be explained?

70. **Influence of Alcohol on the Size of the Heart.**—The question whether alcohol increases the size of the heart has a therapeutic bearing, since if such is the case we would not be justified in using it therapeutically in certain cases where we now employ it. Bickel has experimented as to this point on animals by subcutaneous injection or forced ingestion of alcohol in dogs, then examining the condition of the heart. From his results with the aid of the Moritz orthodiagraphic apparatus he does not prove any enlargement of the heart in animals from the use of alcohol. This result agrees with the observations of Moritz in corresponding experiments on the human being.

74. **Hygiene and Race Degeneration.**—In a long article in this and a preceding number, Gruber takes up the questions which have been raised as to how far hygiene tends toward racial degeneracy. The claim has been made that, like all animals, man as he approaches his natural state undergoes a process of natural selection which benefits the race as a whole, weeding out the unfit, and all the infirmities of civilization are

perpetuated, it is said, by the care we take of our defective individuals. Bad teeth, defective eyesight, hypersensitiveness to temperature, inability to endure hardships are mentioned, and alcohol, too, is said to have a selective action in weeding out the degenerates. Thus the larger the infant mortality the better the surviving specimens. Gruber statistically proves that where the infant mortality is high the adult mortality is also high, and that hygiene, instead of causing race deterioration, seems to be an agency for greater race vitality. He reviews a number of errors which he thinks are more or less common. It is an error, for instance, to assume that a greater sensibility or lessened resistance in all cases must lead to disease and death, and not less an error to speak of an inborn physical incapacity where there is an actual special weakness which causes death. We must consider many other possible factors, and we must remember that every defective individual who is weeded out in consequence of his defects has not necessarily had that defectiveness from his birth or is a born degenerate. It is also unscientific to make any sharp distinction between defectiveness and non-defectiveness as practiced, the one implying destruction and the latter perfection and growth. There is an infinite number of transitional stages between the two. Natural selection is no explanation of the facts as they occur in actual life, and it is poor policy to claim that the strong do not need the benefits of hygienic measures as well as the defective. He makes a special point of this as regards alcohol. While it has a limited selective action, it is nevertheless one of the most tremendous evils to the race. As regards mankind in general, the application of the principle of the struggle for life is not correct, and the improvement of the race will not be by the blind working of natural selection, but by rational race culture the chance for which is afforded to a large extent by the provisions of modern hygiene and civilization.

75. **Treatment of Inguinal Laparocele.**—Garampazzi treats this condition by a method of repair which he describes in full, and states that several of the patients seen years afterward show the permanently successful results of the intervention. He discusses the relations between inguinal laparocele and traumatism and the various modes of operative intervention that have been proposed. He makes a curved incision, the convex side downward, to avoid the tissues in which the sweat and sebaceous glands are most numerous, and draws the layers of the aponeurosis one on top of the other to reinforce the wall, avoiding compressing the elements of the cord. He prepares the aponeurosis by turning back the upper lip of the wound as an ophthalmologist everts the eyelid. This produces a kind of artificial Poupart's ligament, after which he proceeds as for an ordinary Bassini. The lower flap of the aponeurosis is then sutured to the turned-over edge of the everted flap, after which the free edge is turned back into place and sutured.

76. **Saline Transfusion in Influenza.**—Cioffi believes that he is the first to apply this measure in influenza. He reports a case in detail in which the results were surprisingly good. The patient was a woman of 45, and when first seen the pulse was 142 and threadlike, there was great weakness, also dyspnea, progressing to actual collapse with constant vomiting and subnormal temperature for three days, notwithstanding the most energetic measures, caffein, etc. As a last resort, the patient being almost in articulo mortis, 100 gm. of a 7 per cent. salt solution were injected subcutaneously. The benefit was apparent in half an hour, and all the symptoms rapidly improved. There was a chill and slight fever during the evening, but by the next morning the pulse was 80 and strong, temperature nearly normal, and in three days the patient was completely cured.

78. **Simultaneous Ligature of Femoral Artery and Vein.**—Orecchia reports a case of stab wound of the thigh in a healthy young man, in which he found it necessary, in order to control the threatening hemorrhage, to throw a ligature around both the femoral artery and vein. Gangrene developed in consequence, and notwithstanding disarticulation of the limb the patient succumbed. He reviews the cases that have been reported in the literature in which the femoral artery and vein have been ligated. Gangrene followed in 8 out of 15 (Braun), and in 14 out of 24 published by other writers, while Tillmann, Sorrentino and Pilcher have each reported a complete recovery. Orecchia experimented on 8 dogs and found that none of them showed evidences of gangrene after ligature of the femoral artery and vein supplemented in some of the animals by ligature of several other vessels in the vicinity and even by extensive venesection. Dogs are evidently much more resistant than man to such procedures, and it is possible that the vessels tolerate the procedures better in some persons than in others.

83. **Operative Treatment of Varicocele.**—Parona's method has been applied in 41 cases and the results have been perfectly satisfactory in all, with no further necessity for a suspensory. In mild cases, not causing pain nor other disturbance, a suspensory is all that is needed, but when symptoms demand more active treatment, the Parona method is regarded as superior to all others by Viscontini. The testicle is detached from the vaginalis; the enlarged veins are buried in the turned over vaginalis, and the latter is fastened at the outlet of the inguinal canal. The technic was worked out on animals and the remote results examined before it was tried in the clinic—all the evidence being in its favor. The patients can be dismissed in fifteen days. The details of the intervention were published in a previous communication in the *Policlinico*, VI, 1899.

88. **Formaldehyd Test for Albumin in Urine.**—Introna has found that formaldehyd causes the coagulation of albumin in solution and recommends a new test for albuminuria based on this fact. He adds 1 c.c. of formaldehyd to 56 c.c. of urine. If it is free from albumin the fluid remains clear, but in the presence of albumin it becomes turbid and a flocculent precipitate is gradually deposited consisting entirely of the albumin. The test can be hastened by heating to boiling point, in which case the precipitate is deposited without delay. For quantitative estimation by weight he adds 20 c.c. of formalin to 100 c.c. urine and heats for half an hour in the water bath, concluding by the technic of the Scherer test. He also asserts that formol may be substituted for the Esbach reagent in quantitative clinical diagnosis. He tabulates the results of various tests of solutions of albumin of known concentration, comparing them with the results obtained with the formalin. In every instance the exact proportion known to exist was

reproduced with the latter, while the results of boiling and adding acetic acid were always a little below the correct figure.

92. **Kerato-Conjunctivitis Consecutive to Articular Rheumatism.**—Ortale's patient was a healthy man of 30 who passed through a typical attack of articular rheumatism. Some of the joint symptoms have recurred in a mild form occasionally during the months since, and accompanied each time by symptoms of circumscribed kerato-conjunctivitis, which disappear with the joint symptoms.

96. **Functional Heart Affections.**—In the 2 cases reported in detail by Amantini the syndrome was evidently that of a cardiac neurosis in exceptionally nervous subjects. Although exclusively functional, yet the severity of the attacks is liable to induce some dangerous complication, or to entail organic disease in time, some valvular defect or myocarditis, myocardiac insufficiency or general arteriosclerosis. These possible dangers must be borne in mind by the physician and he should aim to keep the digestive tract in good condition and induce such patients to refrain from nervous strain of all kinds. Medicines to act on the heart are useless and even dangerous; the main reliance must be on the avoidance of the inciting causes of the neurosis.

99. **Chronic Pemphigus.**—Secchi's patient was a woman with evidences of malarial cachexia, who entered the clinic on account of recurring attacks of a febrile bullous eruption with the clinical morphology of chronic pemphigus. A staphylococcus aureus was cultivated from the blood which produced merely transient fever and emaciation in a rabbit after intravenous inoculation. From one of the bullæ a streptococcus and staphylococcus aureus were derived which proved fatal for a rabbit in eleven days in intravenous injection. Abscesses were found in the kidney. He explains the case as chronic pemphigus caused by a staphylococcic septicemia consecutive to malaria.

103. **Rapid Method of Detecting Vegetable Poisons in Animal Tissues.**—Di Mattei announced last year that it was possible to determine the nature of some poisons by the characteristic differences exhibited by the precipitates after treatment with Bouchardat's reagent. He now reports that the tissues of animals killed by ingestion of a vegetable alkaloid poison exhibit the same characteristic precipitate reaction as the pure poison alone. Consequently it will be possible to detect poisons in the viscera in forensic cases by this simple test. He cites the peculiarities of each precipitate as observed in extracts of tissues of animals poisoned with strychnin, brucin, veratrin or morphin, etc. Control tests confirmed the specific and differential value of the aspect, color, etc., of the precipitates in the case of each poison. The response to the test was as perfect in tissues from animals that had been dead for five days as in the fresh cadavers. He proceeds by digesting the specimen with alcohol for twelve hours or with water slightly acidulated with tartaric acid, then filtering and evaporating the alcohol. He then adds a little water and induces precipitation with the Bouchardat reagent, concluding by extracting the alkaloid from the precipitate with baryta water to confirm its identity. By this technic it is possible to detect and identify a vegetable alkaloid poison in the tissues in less than two days. [The Bouchardat reagent for alkaloids is a mixture of 10 parts iodin and 20 parts potassium iodid in 500 parts water.—ED.]

THE SURGICAL TREATMENT OF TRAUMATIC HEMORRHAGE OF THE SPLEEN.*

N. SENN, M.D.

Professor Surgery, Rush Medical College; Surgeon-in-Chief, St. Joseph's Hospital; Attending Surgeon, Presbyterian Hospital.

CHICAGO.

The timely and intelligent application of the modern hemostatic resources enables the surgeon to deal successfully with external hemorrhage, but the treatment of visceral hemorrhage from the large vascular internal organs is by no means a closed chapter. Hemorrhage from wounds of the spleen, liver and kidneys is usually profuse, and is more frequently the result of injury to the parenchyma and veins than to the principal artery or its larger branches; in other words, the loss of blood is more frequently due to parenchymatous and venous than arterial hemorrhage. As a rule, the severity of traumatic hemorrhage of these organs bears a direct relation to the degree of their vascularity. The absence of muscular tissue in these organs is largely responsible for the profuseness of the hemorrhage and the difficulties encountered in attempts to arrest it. The severed vessels do not contract; their lumina remain patent, thus maintaining mechanical conditions antagonistic to spontaneous hemostasis by thrombus formation. The great abundance of capillary vessels and the delicate structure of the large veins are other anatomic features adverse to Nature's efforts in arresting the hemorrhage. The friability of the parenchyma of these organs and the thinness of their capsular investment render it difficult to apply the direct hemostatic measures so reliable in arresting hemorrhage from other organs and parts, and for these reasons can not be resorted to here with the same sense of security. Even when these organs, when the source of hemorrhage, are exposed by the accident which caused the visceral injury, or when the visceral wound has been made accessible by incision, the surgeon is often at a loss what course to pursue. As the hemorrhage is often so severe as to place in immediate jeopardy the life of the patient, the surgeon must of necessity act promptly and with decision. Hesitation becomes a source of danger under such circumstances. The spleen is one of the most vascular organs in the body. If the abdomen of an anesthetized dog is opened, the spleen exposed and the animal bled to death by cutting the femoral or common carotid artery, the organ becomes pale and loses two-thirds of its volume before the animal expires. The same reduction in size follows section of the splenic artery. With the increase of the splenic anemia, the parenchyma becomes firmer.

Traumatic hemorrhage of the spleen must necessarily vary in accordance with the size, direction, location and character of the wound. A wound near the hilus of the organ, implicating the principal trunk of the splenic artery, would naturally give rise to a maximum amount of hemorrhage. As a rule, the larger the wound, the severer the hemorrhage. A transverse wound bleeds more profusely than a longitudinal one because it severs more large vessels, the wounds being of the same size. An incised wound bleeds more freely than a lacerated, contused or punctured wound for the same reasons as incised wounds elsewhere. A brief study of the available clinical material applicable to consideration of traumatic hemorrhage of the spleen and its surgical treatment should prove interesting, as well as profitable, at this time.

RUPTURE OF SPLEEN.

E. Berger[1] has collected 168 cases of rupture of the spleen. Deaths occurred as follows:

On the first day	145	86.3 per cent.
Of these, during the first hour	87	51.8 " "
From 2 to 10 hours	43	25.6 " "
From 11 to 24 hours	15	8.9 " "
After the first day	23	13.7 " "
Of these on the second day		4
Of these on the third day		6
Of these on the fourth day		3
Of these on the fifth day		4
Of these on the twelfth and thirteenth day, each		2
Of these on the sixteenth and twenty-first day, each		1

In those who died on the first day hemorrhage was the immediate cause of death, and in some of those who died later, so that not more than in 10 per cent. could infection be regarded as the cause of death.

GUNSHOT WOUNDS.

During the Civil War 253,142 of the Federal Army were wounded, and in only 29 of this immense number wound of the spleen is recorded. During the Franco-Prussian War, of 99,566 wounded of the German army, only 4 wounds of the spleen are mentioned.

Robinson,[2] in his report on 1,596 gunshot wounds in the Philippine campaign, says: "Death in consequence of gunshot wounds of the spleen was the rule. Our statistics show only one recovery."

Sir Frederick Treves refers to one case of gunshot wound of the spleen operated on by laparotomy in the South African War. The patient died on the table.

The number of spleen wounds in military statistics is small because wounds of this organ are usually associated with other grave complications, and only too often

* Presented to the Surgical Section of the Madrid International Medical Congress.

1. Archiv für klinische Chirurgie, Bd. xxviii, Heft 3.
2. Annals of Surgery, February, 1901.

death ensues on the field before assistance can be rendered.

Of 80 cases of gunshot wounds of the spleen collected by Berger from all sources who died without operation, 34 died of hemorrhage on the first day.

Of the cases subjected to surgical treatment, 16.7 per cent. which occurred in military practice and 63.6 per cent. in civil practice usually died of hemorrhage. Death before the fourth day could generally be attributed to hemorrhage; after that time to infection. Infection is again very prone to give rise to secondary hemorrhage.

INCISED AND STAB WOUNDS.

Berger tabulated 40 cases of incised and stab wounds of the spleen. In 10 of the cases the wounded spleen was prolapsed. In 14 cases, without prolapse, surgical treatment was not resorted to; the mortality was 78.6 per cent. Hemorrhage was the predominating cause of death, usually within twenty-four hours. Statistics go to show that the prognosis is much more favorable if the wounded organ is prolapsed.

SURGICAL TREATMENT.

The surgical treatment of wounds of the spleen has been studied with special care by Mayer, Edler and Berger. Berger's[3] painstaking statistical work brings the subject up to the present day. He collected 127 cases of wounds of the spleen treated by laparotomy. Of this number, 90 were subparietal wounds, 18 gunshot and 19 incised and stab wounds. In more than 80 per cent. the indication for laparotomy was hemorrhage. Operation was performed from six to nine hours after injury. In 80 cases the wounded organ was removed, with 35 deaths. Suturing (splenorrhaphy) was done in 14 cases, with 2 deaths. Tamponade was employed in 10 cases, with only one death. In many of these cases there were found other visceral injuries, which made further operative intervention necessary.

SPLENORRHAPHY.

Suture of wounds of the spleen was first performed by Lamarchia in 1896. His patient died of secondary hemorrhage an hour and a half after the operation. In a similar case, Madelung, after suturing the spleen, covered the sutured wound with omentum, and his patient recovered.

CAUTERIZATION.

In a case of a splenic wound which bled profusely Rehn attempted to arrest the hemorrhage by suturing. The bleeding continued, and was finally arrested by the use of the actual cautery. Snegnireff made use of hot steam. The actual cautery has a very limited sphere of usefulness in the treatment of traumatic hemorrhage of the spleen, owing to its uncertainty and the additional destruction of tissue by its use, and the liability of extending the injury inflicted to adjacent organs.

TAMPONADE.

Kelling recommends air tamponade of the peritoneal cavity as a hemostatic for the arrest of visceral hemorrhage. In a dog he divided the spleen transversely, injected air into the abdominal cavity until by intraperitoneal pressure the hemorrhage was completely arrested. He probably would not rely on this method of arresting hemorrhage in the treatment of traumatic hemorrhage of the spleen in the human subject. Gauze tamponade has yielded the best results, and should be given the preference in appropriate cases.

LIGATION OF THE SPLENIC ARTERY.

Ligation of the splenic artery would certainly control hemorrhage from any wound of the spleen, regardless of location and size. It is unfortunate that this radical measure is incompatible with the preservation of the wounded organ, as has been demonstrated by the experiments of Jonnesco and his assistants. Most of the animals operated on by ligating the splenic artery of the intact spleen died of a toxemia which, according to the opinions of the experimenters, was caused by the production of a poison in the substance of the spleen completely deprived of its blood supply. They suggested that this poison found its way into the peritoneal cavity, and from there was absorbed by the lymphatics and entered the general circulation, causing death from acute toxemia. In the few instances of recovery of the animals the spleen became extremely atrophic in less than two weeks.

SPLENECTOMY.

It has been shown by experiments on animals, as well as by clinical observation, that the spleen can be removed without any serious immediate or remote consequences. This well-known fact would naturally suggest to the surgeon the advisability of resorting to excision of the wounded spleen in all cases in which less severe measures promise little or no encouragement in arresting the hemorrhage. Then, too, splenectomy for hemorrhage has a fairly good record. Of the 80 cases tabulated by Berger, in which the spleen was removed for hemorrhage, 35 recovered. Notwithstanding the facts referred to above, it must be contended that ideal surgery is and always will be conservative surgery. The unnecessary removal of any organ for hemorrhage or other lesion amenable to successful treatment by conservative measures is faulty in theory and practice, and should not be encouraged. The spleen has its important functions to perform, and, although in its absence other organs appear to assume its rôle in the organism and compensate for its loss, we as yet are not warranted in assuming that its removal is a matter of so little consequence that it is not necessary to limit it to cases in which no other alternative is left. Splenectomy should be reserved for cases of traumatic hemorrhage of the spleen in which the bleeding can not be arrested by conservative treatment, and in cases in which the visceral injury otherwise is of a nature incompatible with attempts to conserve the damaged organ.

PARTIAL SPLENECTOMY.

Excision of the injured part of the spleen may become necessary in the surgical treatment of hemorrhage of the spleen. Hartin Jordan[4] has made some very interesting experiments which have a practical bearing on this question. He made partial excision of the spleen on 22 dogs. Hemorrhage was controlled by double ligature of the arteries and suturing of the margins of the visceral wound. He found that the lower part of the spleen could be removed without giving rise to any troublesome hemorrhage or serious general disturbances, which could not be said when the entire spleen or its upper part was excised, as ligation of the splenic artery compromises the splenic plexus, which is in intimate relation with the solar plexus.

FORCIPRESSURE OF WOUND MARGINS.

Under slow broad pressure with forcipressure forceps, the pulp of the spleen is displaced from the meshwork of loose connective tissue which, in turn, is condensed into a broad firm band in which the larger blood vessels become entangled, their cut ends contused, and hemorrhage even of branches of the splenic artery of considerable size and large veins is arrested. This method of arresting arterial, venous and parenchymatous hemorrhage has been practiced extensively and with the best results in arresting hemorrhage from other vascular organs and tissues, and is of special value in the surgical treatment of traumatic hemorrhage of the spleen. During the winter of 1902 I made a series of experiments on dogs to test its hemostatic value. A few of these experiments I will relate very briefly here:

EXPERIMENT 1.—This experiment was made solely for the purpose of demonstrating the immediate hemostatic effect of forcible compression in arresting traumatic hemorrhage of the spleen. Dog of medium size. Under ether anesthesia the abdomen was opened, the spleen exposed and a longitudinal incision, three and one-half inches, was made through the entire thickness, causing very profuse hemorrhage. The margins of the visceral incision were clamped with heavy compression forceps, making slow but firm pressure. The immediate effect of the pressure was to squeeze out of the fibrous meshwork of the spleen the pulp, transforming the tissues in the grasp of the forceps into a firm fibrous mass. The hemorrhage was almost completely arrested, and ceased entirely on uniting the crushed tissues with two catgut sutures.

EXPERIMENT 2.—Small dog. Under complete anesthesia the abdomen was opened in the median line by an incision four inches in length. The left lobe of the liver projected into the incision and was incised two-thirds in its anteroposterior diameter. The hemorrhage, which was profuse, was arrested by clamping the margins of the wound. The crushed tissues were sutured together with three catgut sutures, all of which were tied on the convex side. The hemorrhage was completely controlled by the combined process of crushing and suturing. The spleen was then incised deeply in a transverse direction, the wound margins subjected to slow forceps pressure and the crushed tissues sutured with silk. The abdominal incision was closed with six silk through-and-through sutures and the wound sealed. The dog lived four days. Surface of visceral wounds adherent to omentum and parietal peritoneum. An abscess was found in the spleen under the omental adhesions. A silk suture completely detached was found floating in the pus. Nothing abnormal in the liver wound.

EXPERIMENT 3.—Large black bitch. Chloroform anesthesia. Through a median incision the spleen was exposed and an incision, four inches in length, was made in the center of its long axis, dividing the organ nearly into equal halves. In consequence of the profuse bleeding the organ collapsed in a few moments to less than one-half of its normal volume. The hemorrhage was promptly arrested by marginal crushing and the crushed borders united with four strong catgut sutures. One additional suture was placed on the under surface of the spleen to arrest the bleeding from a small point. The animal exhibited no untoward symptoms after the operation, and was killed a week later. External wound completely healed. Spleen slightly enlarged. Wound on both sides covered by adherent omentum. Healing of visceral wound satisfactory and far advanced.

EXPERIMENT 4.—Light brown, medium-sized dog. Through a median incision, four inches in length, the spleen was exposed and its longer but narrower half was deeply incised from the free border in a longitudinal direction. With a pair of long hemostatic forceps the borders of the wound were crushed slowly, with the result of arresting the profuse hemorrhage almost completely. The slight oozing which remained was arrested on uniting the crushed margins with six catgut sutures. Abdomen closed with six silk sutures. The dog showed no indications of indisposition after the operation. The appetite remained voracious and was satisfied by a liberal diet of coarse food. The animal was killed two weeks after the operation. The injured part of the spleen was much enlarged, club-shaped and enveloped by firm adhesions. On palpation distinct fluctuation could be felt. On incision about an ounce of pus escaped. The abscess cavity was circumscribed and well walled off. On closer inspection the cavity was found to be on the surface of the spleen, the anterior wall being formed by the adherent omentum. Beneath the abscess healing of the splenic wound had taken place.

EXPERIMENT 5.—White fox terrier, poorly nourished. Through the usual median abdominal incision the spleen was made accessible and was cut transversely near the hilus, through two-thirds of its diameter. The severe bleeding yielded promptly to crushing of the margins of the wound with a strong pair of hemostatic forceps with wide blades. The crushing was continued for two minutes. With three catgut stitches the crushed edges were sutured. Hemostasis absolute. The behavior of the animal after the operation suggested satisfactory repair of the wound. The dog was killed in three weeks and the postmortem showed that the wound of the spleen had healed in an ideal manner. Size of spleen normal, or nearly so; adhesions few and slight; organ freely movable.

EXPERIMENT 6.—Small male dog. In this experiment the spleen was deeply incised in a transverse direction through its largest part. Under slow marginal pressure with clamp forceps the hemorrhage was quickly and almost completely arrested. The crushed tissues were then united with three catgut sutures and the abdomen closed with three silk sutures. Dog remained in excellent condition when killed, three weeks later. The splenic wound was found healed and covered by omentum. Organ normal in size and freely movable.

EXPERIMENT 7.—Medium-sized bitch. In this instance the spleen was incised longitudinally from the free border to the depth of three inches. The bleeding, which was very profuse, yielded promptly to slow crushing of the wound margins. The blades of the forceps were applied in such a way that about one-fourth of an inch of the margin of the wound escaped from their grasp. A slight oozing which persisted was arrested by suturing together of the crushed tissues with fine catgut sutures. The dog was in perfect condition when killed, four weeks later. Spleen slightly enlarged. Omentum adherent to the surface of the wound. Ideal healing of the visceral wound through the entire length of the incision.

REMARKS ON THE EXPERIMENTS.

These experiments prove the hemostatic value of marginal crushing of wounds of the spleen. All of the wounds made were clean-cut, incised wounds, hence wounds calculated to give rise to a maximum amount of hemorrhage. In all cases the hemorrhage, which was always profuse, was completely arrested by the crushing and suturing of the crushed margins. Secondary hemorrhage never occurred. The postmortem specimens showed invariably adhesions between the omentum and the wound surfaces. In two of the experiments a small localized abscess developed, undoubtedly in consequence of infected ligature material. All of the visceral wounds were large and a considerable amount of splenic tissue was destroyed by the crushing process, but nothing approaching marked atrophy was observed in any of the specimens. Even in the cases in which the organ was divided two-thirds through its transverse diameter near the hilus the distal part retained its vitality, and exhibited no gross lesions in consequence of the diminished blood supply. I am of the opinion that much of the destroyed tissue was replaced by regeneration, as exhibited by the specimens. The regenerative capacity of splenic tissue has been well established by experimental researches made for this special purpose.

The procedure I have described recommends itself in the treatment of certain wounds of the normal spleen,

particularly in incised wounds and straight tears, when a quick hemostasis is a matter of greatest importance. The broad forcipressure can be relied on in arresting the bleeding, consequently further serious loss of blood is prevented the moment the visceral wound has been made accessible. Too much stress can not be placed on the importance of making the compression slowly, as rapid compression is liable to tear the fragile tissue instead of compressing it. With two large hemostatic forceps, both wound margins are compressed simultaneously, thus controlling the hemorrhage the moment they are applied. The crushed margins should be sutured together with catgut. The slight oozing, which sometimes remains, takes place from the crushed tissues, and sometimes yields promptly to the suturing of the

Fig. 1.—Crushing the margins of the wound in the spleen.

compressed borders. Another reason for suturing the wound is to prevent extensive and perhaps harmful adhesions between the wound margins and adjacent viscera. There is also reason to believe that approximation of the wound margins is conducive to an ideal healing of the wound, and subsequent regeneration of the tissues lost by the injury and the operative intervention. As crushed tissue is more liable to infection than vascular tissue, permanent suture material should be avoided.

In discussing the general subject of hemostasis of splenic wounds, it is apparent that no one exclusive

Fig. 2.—The wound sutured.

method of treatment can be relied on. The treatment to be employed must necessarily depend on the location, size and character of the wound, and the condition of the wounded organ. The one great rule that should not be lost sight of, and one which should apply to all kinds of surgical work, is, not to sacrifice any more healthy tissue than is absolutely necessary to meet the indications presented by each individual case. Conservative surgery should take the place here, as elsewhere, of mutilating surgery. The fact that the spleen can be removed in animals without any serious consequences following does not warrant the conclusion that this organ can be sacrificed with immunity. It is true that the spleen has been removed in the human subject for various indications without any apparent ill effect, but cases may occur in which other organs may fail to assume compensatory action. The retroperitoneal hemolymph glands in the renal and other regions might refuse to respond to the need of an additional blood-producing organ. The removal of a wounded healthy spleen is an easy operation, and can always be relied on in arresting the hemorrhage, but these reasons alone would not warrant the removal of the organ if the hemorrhage can be arrested by conservative measures.

The surgical treatment of traumatic hemorrhage of the spleen naturally divides itself into: 1, Splenectomy; 2, partial splenectomy; 3, splenorrhaphy; 4, aseptic tamponade; 5, cauterization; 6, marginal crushing and suturing.

1. *Splenectomy.*—Splenectomy is the operation of necessity in the treatment of traumatic hemorrhage of the spleen, if the organ itself is diseased or in case the wound implicates the main trunk of the splenic artery. If the spleen is enlarged and softened, as is the case after acute infectious diseases, or, in consequence of chronic malarial intoxication, wounds cause very obstinate bleeding, which, owing to the textural changes which have taken place, resists all attempts at hemostasis short of splenectomy. In such an event, no time should be lost in the employment of conservative measures, and the diseased wounded organ should be promptly removed. The same treatment is to be pursued if the wound involves the hilus of the spleen and its principal artery.

2. *Partial Splenectomy.*—If the lower part of the spleen has been extensively crushed or lacerated, or if a transverse wound has divided two-thirds of the diameter of the organ, removal of the injured or partially detached part of the spleen is indicated. The amputation should be done by the use of the crushing forceps, and after excision the crushed tissue should be covered with omentum, which is sutured over it with catgut sutures. Suturing of the omentum over the stump is an additional means of hemostasis, and prevents harmful visceral adhesions.

3. *Splenorrhaphy.*—Suturing as a hemostatic has had a fairly good record, and will be resorted to in appropriate cases. The mattress suture or shoemaker's stitch is best adapted for this purpose. A round needle armed with catgut is to be used for this purpose. Bleeding from the punctures is reduced to a minimum by using the double catgut suture, so as to tampon the tract made by the needle with the suture material, which soon swells by the absorption of moisture. After the hemorrhage has been arrested in this manner, the cut surfaces are sutured together with a few separate catgut stitches. In bullet wounds, a circle of through-and-through mattress sutures will usually succeed in arresting the bleeding. The bullet wound itself in such cases should always be drained with aseptic gauze. If suturing is decided on, further loss of blood should be prevented by digital compression of the injured part of the spleen until the suturing is completed.

4. *Aseptic Tamponade.*—The aseptic tampon is often relied on by the surgeon in the management of troublesome parenchymatous hemorrhage that can not be controlled by more direct means, or when the source of hemorrhage is not accessible to more reliable hemostatic resources. In the case of wounds of the spleen,

this method of arresting the hemorrhage meets with a decided disadvantage in the absence of an adequate resistance to pressure. Notwithstanding the unfavorable mechanical conditions for effective tamponade, this hemostatic agent has given satisfactory results in many cases of traumatic hemorrhage of the spleen, in which it was relied on in arresting the bleeding. It will prove of value if the hemorrhage is venous or parenchymatous, but should never be relied on in bleeding from arteries of any considerable size, that is, in the treatment of arterial hemorrhage. The typical Mikulicz tampon is the one to be employed, as in this case the tampon can be removed with ease, and there is no danger of leaving a part of the tampon in the wound. The tampon also serves the useful purpose of a drain, and should be allowed to remain as long as it is deemed necessary to continue drainage. The size of the tampon can be diminished at any time it is considered safe to do so.

5. *Cauterization.*—The use of the actual cautery in the treatment of traumatic hemorrhage of the spleen has an exceedingly limited sphere of usefulness, if any. It is not reliable, and may inflict serious damage on important adjacent structures. The eschar which it produces interferes seriously with an ideal healing of the visceral wound. For these and other reasons it seems to me that the actual cautery should be resorted to only in exceptional cases as a hemostatic in the treatment of wounds of the spleen.

6. *Marginal Crushing of the Wound and Suturing.*—The most reliable procedure in arresting traumatic hemorrhage of the spleen in all cases in which the wounded organ can be saved is marginal crushing, followed by suturing the crushed margins with catgut. The hemorrhage is arrested the moment the forceps are applied, and the blood vessels in the crushed tissues are speedily obliterated by thrombosis, thus guarding against recurrence of the bleeding, and by uniting the crushed wound margins by suturing with catgut the visceral wound is placed in the most favorable condition for speedy healing and regeneration of the tissues lost by the injury and the operative treatment of the wound.

EXPERIMENTS WITH RENNET AND ANTIRENENE.*

JOSEPH McFARLAND, M.D.
PHILADELPHIA.

In 1899 Morgenroth published a paper entitled "The Antibody of Rennet," containing a description of certain work that he had done in support of Ehrlich's chemical theory of the toxin-antitoxin reaction. So far as I know, Morgenroth's work met with universal acceptance without having been subjected to experimental confirmation, nor did I think it worth while to confirm it or make any addition to what Morgenroth had found until the specific precipitates began to attract attention, when their study led me to experiment with antipeptone, antivenene and antirenene.

The antirenene was prepared solely for the purpose of securing the precipitate, but as I found it possessed the power of inhibiting the coagulant action of rennet on milk, I continued to investigate the subject until I found in it a confirmation of what Morgenroth had done, and found myself able to make a few additional contributions to the subject.

Morgenroth's experiments were performed on goats, which were injected with rennet prepared by Witte in Rostock, the activity of this rennet being 1-3,000,000. The sterility of the rennet solution was secured by the addition of iodin (1 c.c. of a 1-10 iodin solution to each 10 c.c. of the rennet solution permitted to stand 1 hour at room temperature), and no abscesses followed its employment. The goat was given increasing doses of the rennet solution administered by subcutaneous injection until 6.5 grams at a dose were administered. After each injection the temperature rose to about 41.4 C., without any disturbance of the general condition or appetite, and without any observable diminution of the body weight. Of the two goats thus treated, one produced a considerable quantity of the antibody, the other attained an extremely small degree of immunity, although both were subjected to exactly the same treatment.

The observation of Schepilewski, that an injection of sterile rennet produced amyloid disease, was not confirmed, as both of the goats remained healthy for more than a year after the close of the experiment.

Morgenroth's studies of the antirenene were made with the blood serum and milk of the goats. The standard rennet solution for testing the antibody consisted of a watery extract of the rennet powder in a 10 per cent. sodium chlorid solution, to which was subsequently added an equal quantity of glycerin and 10 per cent. sodium salt solution. It was found that such a solution contained 2 per cent. of the rennet powder, and could be kept for more than a year and a half unaltered. The presence of the antibody in the serum was tested on cow's milk saturated with chloroform by a long continued shaking in a shaking apparatus and then preserved in the cold.

The method for testing adopted by Morgenroth was as follows: His rennet had the power of coagulating milk in a proportion of 1 part in 3,000,000, but when the milk received an addition of 2 c.c. of the serum of an immunized goat, a proportion of rennet equal to 1-30,000 failed to produce coagulation, though a proportion of 1-25,000 produced a firm clot, so that the serum had the power to neutralize 100 times the coagulating rennet dose, and to thicken the milk 200 times the usual dose was required.

The serum from the other goat that did not attain a high degree of antirenene was so much less active that 2 c.c. inhibited in a proportion of 1-120,000 only. The antibody was extremely unstable, and when preserved with chloroform and kept in an ice chest, its activity disappeared in a few months.

My own experiments were conducted on a different plan and with different animals. Rabbits were chosen for the experiment, and at weekly intervals were given intraperitoneal injections of considerable quantities of the standard rennet solution. The rennet employed is a granular, dry powder of a yellow-cream color, freely soluble in water and physiologic salt solution. My standard solution consisted of a 5 per cent. solution in physiologic salt solution, saturated with chloretone. This preparation was found to be so stable that its strength did not alter on keeping for several months, and it was so active that 1/2,500 of a c.c. produced a firm coagulum in standardized milk in between one and two hours. The strength was, therefore, equivalent to 1-500,000. Each injection of 5 c.c. given to the rabbit contained 0.25 of a gram of the pure rennet.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

The rabbits on which my experiments were made weighed in the neighborhood of 1.5 kilograms each. Morgenroth does not give the weight of his goats, and I am not sufficiently familiar with goats to know exactly what they weigh, but presume an average goat would weigh about 50 kilograms. This being the case, the goats weighed approximately thirty times as much as the rabbits, and basing the calculation on body weight would presumably endure about thirty times as much rennet. My experiments were conducted without any knowledge as to the quantity of rennet administered by Morgenroth to his goats. On subsequently looking it up I found that the largest quantity they received was 6.5 grams. Since the rabbits received 0.25 of a gram at a dose, the goats on the same ratio should have received about 8 grams. This would suggest that the rabbits should have attained a higher degree of immunity and produced a stronger antibody than the goats, supposing their ability to produce the antibody about equal. We find, however, that the rennet with which Morgenroth performed his experiments had a strength of 1-3,000,000, or six times that of my rennet. It is thus evident that in proportion to their weight, my rabbits did not receive nearly as much rennet as Morgenroth's goats, and it is not surprising that I found the anticoagulant powers of their serum considerably less. This is, however, by no means a necessary inference, as Morgenroth showed that of his goats, one produced a serum whose anticoagulant power was 1-25,000, while the other was only 1-120,000, thus confirming what is a familiar observation to every one who has experimented with antibodies, viz., that different animals treated in the same way attain very different degrees of immunity, and very different kinds of antibodies in the blood.

Three rabbits were employed for the experiment. The first died after a single injection. At the necropsy I found an extensive serofibrinous inflammation of the pericardium, pleura and peritoneum, and with more or less pneumonia. The exudates contained several different bacteria. The second animal endured about five injections and then died with identical lesions. In the exudates and blood several different bacteria were found. Both the animals seemed to die early in the night, and when bacterioscopic examination showed that several bacteria were present in the exudates, it was not thought worth while to endeavor to isolate the one responsible for the infection. It is interesting to notice, however, that fibrinous exudates occurred in both these animals.

The third rabbit survived a number of injections of 0.25 of a gram of the rennet and was finally bled to death, the serum being carefully separated for study, and extracts of the different organs of the body made in order to determine whether either rennet or antirenene might be contained in the tissues. For this purpose extracts were made of the medulla oblongata, kidney, liver, pancreas, adrenal, bone marrow, lung, voluntary muscle, stomach, large intestine and small intestine. These extracts were prepared by adding to each fragment of tissue ten times its weight of physiologic salt solution (a gram was considered equivalent to 1 c.c. of salt solution). The organs were finely crushed in a mortar, being reduced to a pulp before the salt solution was added. The mixture was then placed in a test tube and kept in the cold over night. The rabbit, therefore, furnished blood serum, organic extracts and urine for further study.

In order that the investigations might be accurate, it was necessary to standardize the milk, and for this purpose chloroform and formaldehyd were first tried. The chloroform was found to be less reliable than was hoped, and the formaldehyd was found to diminish the coagulability of the milk. I, therefore, tried chloretone and found that by saturating the milk with this I was perfectly able to protect it against subsequent microorganismal contaminations, without in any way inhibiting its coagulating power.

As the layer of cream which soon rises and covers the surface of milk kept at the temperature of the body interferes with determining whether the milk has thickened from the presence of the rennet, I found it expedient to use "separator milk" from which the cream was removed. The reaction of the milk affects the action of the rennet; acid milk coagulated much more completely than neutral or alkaline milk. By securing milk fresh from the dairy and immediately saturating it with chloretone, I was able to secure a sufficiently accurate standard, as there was very little variation in the reaction of fresh separator milks, and the saturation with chloretone prevented the development of acidity by bacterial action. The reaction of the milks employed was acid, the acidity varying from 16 to 18 c.c. of normal caustic soda solution being required to neutralize one liter. The difference was so slight that though we tested it carefully it did not in any way seem to modify the action of the rennet, and it is thought not worth while to correct it.

It is well known that the temperature affects the action of rennet, which is much more energetic at high than at low temperatures. Morgenroth preferred to afford his rennet twenty-four hours in which to effect coagulation, keeping the milk in the meantime on ice. Inasmuch as we had eliminated the possibility of any bacterial change in the milk, we were able to keep it at the temperature of incubation, and found that 0.000002 of a gram of rennet added to 10 c.c. of milk invariably produced a firm clot in between one and two hours. We, therefore, adopted the temperature of 37 C. as a standard for the experiments.

In studying the action of the antibody we, therefore, had the following standard conditions:

1. A solution of rennet of which 0.000002 of a gram invariably coagulated 10 c.c. of milk kept at 37 C. in between one and two hours.

2. Milk of a reaction necessary for the appropriate action of the rennet and perfectly preserved from bacterial contamination or alteration either from the production of enzymes or the formation of acids, by saturation with chloretone. (Of this milk, 10 c.c. were used for each test).

The first series was an endeavor to determine whether the rennet injected into the animal was stored up in any of its tissues, and for this purpose 2 c.c. of each of the tissue extracts prepared was added to 10 c.c. of milk and incubated the appropriate length of time. This experiment we made as soon as the extract was prepared.

Table 1.—The Following Mixtures Were Permitted to Stand for 12 Hours:

10 c.c.	Milk	+	1 c.c.	Extract of	Kidney (freshly prepared)	=0
"	"	+	"	"	Liver	=0
"	"	+	"	"	Pancreas	=0
"	"	+	"	"	Adrenal	=0
"	"	+	"	"	Bone marrow	=0
"	"	+	"	"	Lung	=0
"	"	+	"	"	Voluntary muscle	=0
"	"	+	"	"	Brain	=0
"	"	+	"	"	Blood serum	=0
"	"	+	"	"	Urine	=0
"	"	+	"	"	Large intestine	=0
"	"	+	"	"	Small intestine	=+
"	"	+	"	"	Stomach	=+

The coagulation produced by the extracts of stomach and small intestine probably depends on

the presence of rennet naturally formed in the stomach. No rennet existed in any of the other extracts, in the blood serum or in the urine. A similar series was made after permitting the sodium chlorid solution to act on the crushed organs for about 20 hours.

TABLE 2.

10 c.c. Milk + 1 c.c. Extract of Kidney*	=0
" " + " " " Liver	=0
" " + " " " Pancreas	=0
" " + " " " Adrenal	=0
" " + " " " Bone marrow	=0
" " + " " " Lung	=0
" " + " " " Voluntary muscle	=0
" " + " " " Brain	=0
" " + " " " Blood serum	=0
" " + " " " Urine	=0
" " + " " " Large intestine	=0
" " + " " " Small intestine	=0
" " + " " " Stomach	=0

* After 24 hours' maceration.

The next experiments were made for the purpose of determining whether any of the organic extracts contained important quantities of antirenene, and were made with extracts which had been allowed to stand in the cold for about twenty hours.

TABLE 3.—THE FOLLOWING WERE PERMITTED TO STAND FOR 3 HOURS:

10 c.c. Milk + 1 c.c. 20-hour Extract of:	
Kidney + rennet 0.000002 gr.	=+
Liver + rennet 0.000002 gr.	=+
Pancreas + rennet 0.000002 gr.	=+
Adrenal + rennet 0.000002 gr.	=+
Bone marrow + 0.000002 gr.	=+
Lung + rennet 0.000002 gr.	=+
Voluntary muscle + rennet 0.000002 gr.	=+
Brain + rennet 0.000002 gr.	=+
Large intestine + rennet 0.000002 gr.	=+
Small intestine + rennet 0.000002 gr.	=+
Stomach + rennet 0.000002 gr.	=+

Although these experiments were crudely made, they seemed to indicate the absence of important quantities of antirenene in the tissues of the rabbit's body. It might be well to remark that the softest coagulum in the series was that in the tube to which the bone marrow had been added.

The next experiments were made to determine the ability of the blood serum to inhibit the action of the rennet. I find that my method of experimentation differs markedly from that of Morgenroth. Morgenroth used a measured quantity of milk containing an equal proportion of serum and added varying quantities of the rennet. I preferred to experiment by a method more nearly resembling that by which the antitoxic unit is determined in the estimation of the value of antidiphtheritic and antitetanic serums. I, therefore, employed 10 c.c. of milk to which was added exactly the quantity of rennet known to effect its coagulation, and then varying quantities of serum, until I determined the least quantity that would inhibit coagulation.

TABLE 4.—DURATION OF THE EXPERIMENT 3 HOURS. TEMPERATURE 37 C.

10 c.c. Milk + 0.00002 gr. rennet + serum 1 c.c.	=0
" " + " " " + " 0.7 c.c.	=0
" " + " " " + " 0.6 c.c.	=0
" " + " " " + " 0.5 c.c.	=0
" " + " " " + " 0.4 c.c.	=0*
" " + " " " + " 0.3 c.c.	=0†
" " + " " " + " 0.2 c.c.	=+
" " + " " " + " 0.1 c.c.	=+
" " + " " " + " 0.09 c.c.	=+
" " + " " " + " 0.08 c.c.	=+
" " + " " " + " 0.07 c.c.	=+
" " + " " " + " 0.06 c.c.	=+
" " + " " " + " 0.05 c.c.	=+
" " + " " " + " 0.04 c.c.	=+
" " + " " " + " 0.03 c.c.	=+
" " + " " " + " 0.02 c.c.	=+
" " + " " " + " 0.01 c.c.	=+
" " + " " " + " 0.001 c.c.	=+
" " + " " " + " 0.0005 c.c.	=+
Control 10 c.c. milk + 0.00002 gr. rennet + serum	=0

* Soft clot. † Very soft clot.

In this way I showed that the serum effected a distinct inhibition of coagulation, causing the rennet to become inactive in tubes containing 0.5 c.c., or more, of the serum.

The next series of experiments had to do with the specific precipitate, which I expected to find much more delicate, as a means of determining the presence of the antibody rather than the interference with coagulation. Dilutions of the serum and rennet in which the proportions were known, were prepared, placed in small test tubes and kept at the standard temperature. The result was not delicate, as I had anticipated, as is shown by the following table. The quantities of rennet and serum were each diluted with several cubic centimeters of physiologic salt solution, poured together, well shaken, placed in a narrow test tube, and incubated for twenty-four hours:

TABLE 5.

0.00002 gr. rennet + 0.4 c.c. serum	=+
" " " + 0.3 c.c. serum	=+
" " " + 0.2 c.c. serum	=+
" " " + 0.1 c.c. serum	=+(?)
" " " + 0.01 c.c. serum	=0
" " " + 0.005 c.c. serum	=0
" " " + 0.0033 c.c. serum	=0
" " " + 0.0025 c.c. serum	=0
" " " + 0.002 c.c. serum	=0
" " " + 0.001666 c.c. serum	=0
" " " + 0.00142 c.c. serum	=0
" " " + 0.00125 c.c. serum	=0
" " " + 0.0011 c.c. serum	=0
" " " + 0.001 c.c. serum	=0

The large quantity of serum required to inhibit the action of the rennet perplexed me, as it seemed not to be in keeping with what was known about other antibodies. It, therefore, occurred to me that the action of the rennet on the milk might take place too rapidly to afford anything but an overwhelming quantity of the serum an opportunity to inhibit it, and that if I would make mixtures of rennet and the antibody in varying proportions and permit them to stand at the temperature adopted for the standard for a number of hours, the rennet might be destroyed by the antibody in very much smaller quantities than was necessary when both were immediately added to the milk. I, therefore, prepared a number of such mixtures and a correspondingly great dilution of rennet, permitted them to stand over night in the incubator and then added the appropriate quantities to the milk. The result showed that under these conditions the action of the antibody on the rennet was very energetic and entirely confirmed by expectations. Instead of requiring 0.5 c.c. to inhibit coagulation, I now found 0.0005 c.c. to be sufficient, this being the least quantity investigated.

TABLE 6.—TIME, 3 HOURS. TEMPERATURE, 37 C. CONTROL. 10 C.C. MILK + (0.00002 GR. RENNET INCUBATED 24 HOURS) =+.

10 c.c. milk + (0.00002 gr. rennet + 0.4 c.c. serum)	=0
" " + " " " + 0.3 c.c. serum)	=0
" " + " " " + 0.2 c.c. serum)	=0
" " + " " " + 0.1 c.c. serum)	=0
" " + " " " + 0.01 c.c. serum)	=0
" " + " " " + 0.005 c.c. serum)	=0
" " + " " " + 0.0033 c.c. serum)	=0
" " + " " " + 0.0025 c.c. serum)	=0
" " + " " " + 0.002 c.c. serum)	=0
" " + " " " + 0.00175 c.c. serum)	=0
" " + " " " + 0.001425 c.c. serum)	=0
" " + " " " + 0.001225 c.c. serum)	=0
" " + " " " + 0.00111 c.c. serum)	=0
" " + " " " + 0.001 c.c. serum)	=0
" " + " " " + 0.0005 c.c. serum)	=0

I was very anxious to determine how much less than this quantity would inhibit the coagulating power of the rennet. But at this point my experiments were interrupted by pressure of other work and the matter was dropped for several weeks. When I was able to return to it again, I found that what Morgenroth had discovered regarding the instability of the antirenene was correct, and that my serum had entirely lost its power, either when added to the milk or when added to the rennet, to interfere with coagulation.

SUMMARY.

The experiments confirm Morgenroth's discovery that the repeated introduction of rennet is followed by the formation of an antibody inhibiting its action. They show that properly prepared mixtures of rennet and antirenene give a specific precipitate, and show, I think for the first time, that the action of the antirenene is infinitely more active when the two are mixed and allowed to stand for some time before being added to the milk than when immediately added to the milk.

This is in thorough keeping with what was observed by Martin and Cherry regarding the interaction of venom and antivenene. I am also able to confirm Morgenroth's observation of the instability of the antibody.

DISCUSSION.

DR. JOSEPH MCFARLAND, Philadelphia—After the use of the chloretone in the milk I found that I was able to keep the milk as long as I liked. Owing to the negligence of the attendant in not cleaning up the bottles on the stand in my laboratory some of them stood for eight weeks without contamination. The milk simply dried up. I have found chloretone one of the best reagents for the preservation of serums, milks, urines and organic extracts from bacterial contamination. Bacteria will not grow in any of these when the chloretone has been added and there is no injurious chemical action.

DR. L. HEKTOEN, Chicago—I would like to inquire whether the rabbit serum has any coagulative power.

DR. J. W. FOSS, Phoenix, Ariz.—Will anything short of a saturated solution of chloretone act as a preservative?

DR. JOSEPH MCFARLAND, Philadelphia—Replying to the first question, normal horse serum contains a body that slightly inhibits the coagulative power of rennin, but rabbit serum does not.

As to the chloretone, I always use the saturated solution because that is the easiest to prepare.

THE PROTOPLASMIC ACTIVITY OF THE RENAL EPITHELIUM,

AS DETERMINED BY THE ELIMINATION OF PIGMENTS INJECTED INTO THE CIRCULATION.*

INTRODUCTION.

The question of the functional activity of the renal epithelium is ever one of deep interest, both to the physiologist and to the pathologist.

It will be remembered that Bowman's theory concerning the separation of the urine by the kidney was originally founded on anatomic findings entirely and not on experimental evidence. According to this view, the glomeruli separate the watery portion of the urine and the freely diffusible substances, while the specific ingredients of the urine, viz., the urea, uric acid, etc., are secreted by the cells of the uriniferous tubules.

Bowman's theory was replaced for a time by that of Ludwig when the latter investigator and his school showed the close relationship which exists between the circulation of blood in the kidney and the amount of urine separated. This theory held that the separation of urine by the kidney is purely a physical process, the blood-pressure in the glomerular capillaries causing all the ingredients of the urine to filter through into Bowman's capsule in very dilute solution. During the passage of this dilute solution down the uriniferous tubules the water was supposed to diffuse back from the urine into the lymph, so that the urine becomes more concentrated as it enters the pelvis of the kidney.

Further investigation of the subject soon showed that alterations in the general arterial blood-pressure do not always cause corresponding changes in the amount of urine formed, while the latter may be influenced by conditions which do not affect the former. These facts called the first part of Ludwig's theory seriously into question. The latter part, pertaining to the diffusion of water from the uriniferous tubules into the lymph, was demonstrated to be impossible, as the urine has a greater osmotic pressure than the lymph, and if any diffusion takes place, the water would pass in the opposite direction to that contended by Ludwig.

Heidenhain then put forward a theory which is in part a revival of Bowman's hypothesis in that the specific ingredients of the urine are held to be secreted by the protoplasmic activity of the cells lining the uriniferous tubules. Heidenhain went still further and held that the water and freely diffusible constituents of the urine are secreted by the flat epithelium covering the glomeruli and that these are not merely filtered by a physical process alone, although the influence of changes in the general or local circulation on the flow of urine is fully recognized.

Both of these theories have been modified from time to time, and while there may be minor differences, there are two main views held at the present time as to the functional activity of the kidney:

(1) *The Filtration-Absorption Theory* or *Modified Ludwig's Theory.*—This holds that all the ingredients of the urine in very dilute solution are filtered through the capillary wall and the epithelium covering the glomerulus, and that the water and chlorids are absorbed by the cells lining the uriniferous tubules, while the urea, uric acid, phosphates, sulphates, etc., pass on to the pelvis of the kidney in more concentrated solution.

According to this view, the epithelium of the uriniferous tubules is not excretive, but is only concerned in absorption. These cells are supposed to have a selective power in absorbing certain ingredients like the chlorids, while other diffusible substances like urea pass on. If this theory be correct, Heidenhain calculated that fully 70 kilos of water must filter through the glomeruli daily.

(2) *The Excretory, Vital,* or *Bowman-Heidenhain Theory.*—It is contended by those who hold to the other explanation of the function of the kidney that only the water and inorganic salts are separated by the glomeruli. The glomerular epithelium is supposed to be permeable to certain substances and not to others, so that the fluid which collects in the capsule of Bowman contains the inorganic salts in the relative proportion in which they occur in the urine. The cells lining the tubules, and especially those of the contorted tubules, are held to separate the specific ingredients of the urine by an excretory action, i. e., by a protoplasmic activity similar to the secretory activity of other glands.

The main point at issue betwen these diverse views is whether the renal epithelium is absorptive like that lining the intestine, or excretory in function. If the former is correct, then water and salts are absorbed from the urine into the lymph; if the latter is correct, then the metabolites and possibly some of the salts of the urine are separated by protoplasmic activity from the lymph into the urine as it passes down the tubules.

In trying to determine which of these theories is correct most of the work in recent years has been carried

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

on by studying the molecular concentration of the urine under different conditions and comparing it with that of the blood. Much has also been done in studying the action and elimination of different salts.

Unfortunately, there is no ingredient of the urine which can be traced through the renal epithelium by microchemical methods. Bowman[1] and Von Wittich[2] described the presence of uric acid crystals in the epithelial cells lining the uriniferous tubules of birds, but it has since been contended by Schmidt[3] that these observations are incorrect, and that uric acid crystals only occur within the lumen of the tubule and on, but not within, the protoplasm.

Heidenhain[4] made use of a soluble stain which can be injected into the circulation without any harm and can be precipitated in the kidney by perfusing it with absolute alcohol. Sodium sulphindigotate (indigo carmine), when injected into the circulation, appears in the urine in from 2 to 3 minutes. Heidenhain found that if the kidney be quickly excised 5 minutes after the injection of the stain and perfused with absolute alcohol, the pigment is precipitated chiefly in the medulla of the kidney. When the spinal cord was cut prior to the injection so as to lower the blood-pressure and thereby stop the flow of urine, he found the pigment chiefly in the cortex and on microscopic examination found the precipitated pigment granules principally within the lumen of the convoluted tubules, and to a less extent in the epithelial cells lining them.

Heidenhain concluded from these experiments that this pigment is eliminated by an excretory activity of the cells lining the convoluted tubules. While it does not necessarily follow from this that urea is excreted in the same way, nevertheless, this would seem highly probable from the large proportion of this metabolite in the urine if such excretory activity can once be positively established.

Other experimenters have not always obtained the same results from injecting indigo carmine that Heidenhain did. The results obtained with this dye are extremely variable, but admitting that they are uniform, quite a different interpretation has been placed on them. The pigment precipitated in the kidney has been found to occur chiefly in the lumen of the uriniferous tubule and in that part of the renal epithelium which immediately borders on the lumen. It does not occur in such abundance in these cells toward the basement membrane. It is contended by some[5] that the presence of these granules in this part of the cell might be due to absorption from the urine within the tubule as readily as to excretion from the lymph into the urine. This view is rendered more plausible by the fact that by varying the conditions of the experiments the glomerulus is often found to be stained.

PLAN OF EXPERIMENTATION.

The experiments presented in this paper were undertaken with the idea of attempting to clear up this point, viz., whether the protoplasmic activity of the renal epithelium is concerned in absorption or in excretion in the elimination of pigments injected into the systemic circulation.

Different methods were used to stop the free flow of urine with the idea of diminishing the amount of water separated by the glomeruli without interfering with the protoplasmic activity of the epithelium lining the tubules. In one experiment the spinal cord was cut so as to lower the blood-pressure and thereby stop the flow of urine. In two others advantage was taken of the anuria from surgical shock. It is a matter of common experience in performing experiments on the kidney that often the urine does not flow for a considerable time after a kidney or ureter has been exposed, and at times it is necessary to inject a diuretic or physiologic salt solution to establish the flow. As the amount of pigmentation of the kidneys varies in different animals considerably, even when the conditions of experimentation are identical, it is obviously desirable to stop the flow from one kidney without interfering with its circulation, while the other one continues to act normally. This is far preferable to the method of stopping the flow in both kidneys, as it allows comparison in the same animal.

In three experiments one renal artery was compressed between the fingers for one-half to one minute at a time and repeated if necessary. This usually causes a temporary cessation in the flow of urine without interfering with the blood supply, as no injury is done to the artery. Unfortunately, when fluids are subsequently injected the flow of urine sometimes starts again, but is never as great as on the normal side.

In eight experiments the ureter of one side was connected with a mercury manometer by means of a cannula and the urine allowed to flow until the mercury in the manometer ceased to rise. It requires a pressure of 30-40 mm. Hg. to stop the flow of urine. In this way the ureter and pelvis are distended and the outflow from the uriniferous tubules is thus obstructed and comes to a standstill. Normally the pressure in the ureter necessary to stop the flow of urine does not exceed 40 mm. Hg., but under the influence of diuretics it may go as high as 60 or 70 mm. of Hg.

Several of my experiments were performed before the publication of Cushny's paper[6] on the elimination of salts by the kidney when the ureter is obstructed, and until then my attention had not been called to the interference with the renal circulation by obstructing the ureter. Lindemann[7] showed that a pressure of 100 to 200 mm. of Hg. in the ureter causes the kidney to swell up and interfere seriously with the renal circulation, as the outflow of blood from the renal vein is greatly diminished, but if this pressure does not exceed 50 mm. Hg. the venous outflow is not reduced by 10 per cent. In my later experiments a T cannula was tied in the obstructed ureter after a method devised by Cushny, so that one arm could be connected with a manometer, while a short piece of rubber tubing on the other arm, with a screw pinch cock, allowed the urine secreted under pressure to escape and in this way the pressure was kept uniformly between 35 and 40 mm. of mercury.

An effort was made to see if the protoplasmic activity of the renal epithelium could be lessened by atropin. It is supposed by some that this alkaloid checks the renal activity in the same way that it does that of most other glands. Careful urea determinations were made of the urine collected from the ureters for five-minute periods before and after the administration of atropin in three experiments, but there was no diminution in the quantity of urine or of urea, although the flow of saliva was completely stopped and could not be excited in any way.

Pilocarpin also fails to increase the amount of urine or of urea.

SELECTION OF A SUITABLE PIGMENT.

Experiments with sodium sulphindigotate (indigo carmine) are so extremely variable that satisfactory results were never obtained, although it has been tried in nine experiments not included in this paper. Care was taken to repeat exactly the conditions as described by Heidenhain, but the trouble seems to lie in the composition of the pigment and the change which it undergoes under the influence of the living tissues. The living cells appear to reduce it to a colorless substance. This change is so great that even though the kidney is colored blue when it is first cut out and perfused with absolute alcohol, it soon loses color, and sections mounted from it show no color granules. The pigment was the purest obtainable from different sources, but the results were always the same, even though large amounts were injected (5 c.c. to 7.5 c.c. of saturated solution per kilo of body weight).

Starling[5] recommends the use of carmine dissolved in a weak solution of sodium hydroxid. Carmine has the advantage of being more complex in its composition and less diffusible, so that it can be traced through the tissues more readily. It is also very much more stable; is not reduced by the tissues, and can be more completely precipitated by absolute alcohol than can indigo carmine.

The only disadvantages of carmine are its comparative insolubility and the effect of the sodium on the circulation. A saturated solution in weak NaOH solution rarely contains more than 1 per cent. of carmine, and may contain much less if made hastily. When such a solution is rapidly injected directly into the vein it causes the heart to beat slowly and a fall of pressure ensues. This can be obviated by making the injection slowly, and with this precaution from 5 c.c. to 7 c.c. of a saturated solution of carmine in 0.1 per cent. NaOH may be injected for each kilo of body weight. It is very essential that the solution be freshly prepared, as it decomposes very readily.

To avoid the effect on the heart of any free alkali, commercial sodium carminate was tried, but proved less satisfactory than a fresh solution of carmine. The tissues were not so deeply stained and the stain was more diffuse and not so completely precipitated by absolute alcohol.

Sometimes when carmine has been injected into the circulation the urine and kidneys remain remarkably free from the pigment, although the other tissues are stained and the blood-pressure has remained normal throughout. This caused us to try other materials which can be used for the microchemical examination of tissues.

As large amounts of potassium ferrocyanid can be injected directly into the circulation without any injurious effect, this salt was used, and after it had appeared in the urine the kidneys were excised and perfused with a weak solution of ferric chlorid containing a little free HCl. The entire organ turned blue after a time, but sections showed a diffuse stain in some places, with deeply stained material in the lumen of the straight tubules. The results were less satisfactory than those obtained with carmine.

The injection of a soluble salt of iron (citrate of iron and ammonium) was next undertaken, and after the iron had been found in the urine for some time the animal was killed. One kidney was then perfused with a weak solution of ammonium sulphid, and the other was cut into very thin pieces and placed in a weak solution of potassium ferrocyanid acidulated with HCl. The kidneys showed marked precipitates of black in the one kidney and blue in the other, but microscopic sections of the organs were not as satisfactory as those made from experiments in which carmine was used.

Recently a freshly prepared liquor carmini (U. S. P.) has been used. This is a 6.5 per cent. solution of ammonium carminate from which all free ammonia has been driven off by gentle heat or gaseous diffusion. It has the advantage that it contains much more carmine than is possible to get in solution otherwise, and does not lower the blood pressure if injected slowly. It has the disadvantage over a solution of sodium carminate that it increases the flow of urine, probably in the same way that saline diuretics do, as it contains 35 per cent. of glycerin. This also causes a more diffuse staining of the glomeruli than is seen after the injection of the other pigments, although two parts of physiologic salt solution were added to the liquor carmini for injection. At first 5 c.c. or 6 c.c. of liquor carmini per kilo of body weight were injected, but this causes such diffuse pigmentation that 4 c.c. per kilo is a better proportion. Less than this does not give such good results.

In the experiments with carmine and indigo carmine the kidneys were perfused with absolute alcohol through cannulæ tied in the renal arteries. At first this was done with a syringe, but it was found much better to make the injections by gravity, using a separating funnel at a height of about six feet and allowing the absolute alcohol to perfuse for an hour, the kidney being covered with alcohol. The alcohol flowed freely from the renal vein and some escaped from the ureter. The organ was then cut open and thin pieces were placed in a large excess of absolute alcohol. These were then imbedded in paraffin and mounted unstained, so that none of the pigment could diffuse out.

When comparisons were made between the two kidneys the cannulæ of the two renal arteries were connected by a Y tube with one column of alcohol, so that the pressure and amount of absolute alcohol perfused were as nearly equal as is possible to obtain.

In precipitating the iron and potassium ferrocyanid in the kidney the precipitating solution was perfused by gravity and the tissues were then fixed by absolute alcohol and mounted in the same way.

One important fact to remember in this connection is that the vasa recta (i. e., the arterial twigs running between the straight uriniferous tubules) receive much more alcohol when the kidney is perfused than the capillaries about the convoluted tubules. I have determined this definitely by injecting a gelatin mass colored with soluble Prussian blue, with exactly the same pressure and conditions used for perfusing with alcohol. The kidney was warmed by perfusing with physiologic salt solution at 40 C. and it was kept covered with the same. When the gelatin was perfused it flowed freely from the renal vein and the pelvis and ureter were colored blue. The gelatin was then made to set by plunging the kidney in very cold physiologic salt solution, while the pressure in the renal artery was kept up.

On section the blue was found chiefly in the vessels between the straight tubules, in the interlobular arteries and in the capillaries of the glomeruli, but not in the second set of capillaries (renal portal capillaries) about the contorted tubules. This may account for the more complete precipitation of pigment in the straight tubules, and especially just at the junction of the cortex

with the medulla. It is here that the greatest amount of pigment is found precipitated in these experiments.

THE ELIMINATION OF THE PIGMENT.

Indigo carmine, potassium ferrocyanid or carmine may be detected in the urine flowing from the ureter in from two and a half to three minutes after it has been injected into the jugular vein. In the case of iron it requires a slightly longer time—from four to five minutes. The tissues are all diffusely stained after the injection of carmine or indigo carmine. When the kidney is cut open after it has been perfused so as to precipitate the dye, it is seen to be deeply colored, mostly in the medulla and where the latter joins the cortex. On section most of the pigment is found within the uriniferous tubules. The question at once arises, is this pigmentation merely the result of diffusion, or is this foreign substance eliminated by the kidney and gotten rid of in this way?

In the case of carmine it can at once be stated that this is an excretory activity and not merely a diffusion. This statement is based on the observation that pigment granules can be seen within the epithelial cells of the organs of excretion, viz., the kidney, liver and colon, while we do not find them in the cells of the pancreas, spleen or muscles. When moderate amounts of the pigment have been injected these granules do not occur in the cells lining the stomach or small intestine, although the vascularity of all these tissues is fully as great as that of the excretory organs. Furthermore, the contents of the colon and sigmoid flexure show the presence of the dye, while the contents of the stomach and small intestine are not colored unless very large amounts of carmine have been injected. Sections of the tissues not concerned in the elimination of the stain show the pigment granules within the blood-vessels and perivascular lymph spaces, but not within the cells of the parenchyma.

THE MANNER OF ELIMINATION BY THE KIDNEY.

Attention may next be directed to determining whether the elimination by the kidney is the result of filtration through the glomeruli or the result of a protoplasmic activity of the epithelium lining the uriniferous tubules. Neither one of these processes precludes the possibility of the other, and both may operate at the same time. This is often lost sight of by those who endeavor to prove a favorite theory.

When a kidney is removed one-half hour after the injection of carmine into the systemic circulation; is perfused with absolute alcohol for an hour in the manner before mentioned, so as to fix the cells and precipitate the stain *in situ;* and is then imbedded, sectioned and mounted in agents which can not dissolve the stain, most of the pigment is found in the straight tubules of the medulla and those of the medullary rays reaching from the medulla into the cortex. The convoluted tubules of the cortex contain less pigment and it only occurs in places while the glomeruli are quite free from it.

The precipitated carmine occurs chiefly in the lumen of the convoluted tubule and in that part of the epithelial cells which borders on the lumen. The part of the epithelial cells which is nearest the basement membrane is not free from pigment, but with the low power appears to be uniformly tinted.

As stated before, this condition is taken to indicate absorption by those who hold to the filtration theory, while it is interpreted as evidence of excretory activity by those who hold the Bowman-Heidenhain theory.

The experiments presented in this paper seem to indicate that these granules are in the process of excretion rather than of absorption. This view is based on the following facts:

1. The pigment in the renal epithelium of the contorted tubules is found chiefly, but not exclusively, in the part bordering on the lumen. If these cells be examined with a high power (1/12 oil immersion lens), the basal part shows not only a diffuse stain, but fine carmine granules. These can be found not only in cells containing large granules, but in many cells in which there are no coarse granules near the lumen. The difference in the size of these granules is fully as marked as the variation in the size of the neutrophile and eosinophile granules of leucocytes. Why is there this difference in the size of these precipitated carmine granules?

It has been pointed out that in perfusing the kidney with a pressure sufficient to cause a free flow from the renal vein, the vasa recta and the interlobular arteries receive most of the perfused fluid, while the capillaries about the convoluted tubules receive very little. Some of the perfused fluid filters through the blood-vessels of the glomeruli and escapes from the uriniferous tubules into the ureter even when absolute alcohol is used. It would seem possible, therefore, that the pigment is more completely precipitated in the straight tubules and outer part of the convoluted tubules than in the basal part of the latter. This would only explain the difference in the size of the granules, but not the difference in the amount of pigment in these two parts of the cells lining the contorted tubules.

This difference in the distribution of the pigment does not necessarily indicate that it is absorbed by these cells. It will be recalled that in the mammary gland during active secretion the fat globules accumulate in that part of the cell next to the lumen of the acini, and are not uniformly distributed in the part near the basement membrane. The same thing is true of the zymogens of most glands which pour out external secretions. No one would contend from this condition alone that these products of gland activity are absorbed and not secreted.

2. Against the view that these pigment granules are being absorbed, we would point to the fact that some cells in the liver and many cells in the colon show the presence of such granules. If the amount of carmine injected is very large this pigment is also found in the epithelial cells lining the stomach and intestine, but when moderate amounts are used the dye is excreted chiefly by the kidneys and colon. The contents of these hollow viscera show that the carmine is excreted. Other tissues such as the pancreas and spleen, which are just as vascular, do not show the carmine granules in the cells. It can not be contended that the carmine granules in the cells lining the alimentary tract are being absorbed. It is much more probable that the epithelial cells of the uriniferous tubules like those of the colon are active in excreting this foreign substance from the blood.

3. If the ureter be obstructed so that the outflow of urine is stopped without interfering with the circulation of the kidney, the renal epithelium is free to act while the separation of fluid by the glomeruli is reduced to a minimum. When carmine is injected under these circumstances the amount of pigment in the obstructed kidney is much greater than in the normal one. The cortex is more deeply colored than in the unobstructed kidney, but still contains less than the medulla. Sections show most of the pigment in the lumen, as very

little is flushed out. The amount of pigment in the cells of the contorted tubules, and especially toward the basement membrane, is relatively increased. It might be contended that this is due to increased absorption under pressure, but the concentration of the urine which accumulates in the pelvis of the kidney when the ureter is obstructed argues strongly against the view that a dilute urine continues to be actively separated by the glomeruli when the ureter is obstructed. This has been determined by comparing the amounts of urine and urea respectively given off by the normal and by the obstructed kidney. My own experiments are not in accord with those of Cushny on this point.

3. When the free flow of urine is stopped by cutting the spinal cord and thereby lowering the blood-pressure, or as the result of surgical shock, or as the result of compressing the renal artery for a short time without injuring the intima, the injection of carmine into the circulation results in far more of this pigment being found in the uriniferous tubules and in the cells lining them than could be accounted for by a slight transudate which might continue from the glomeruli with complete resorption of the water. Indeed, when the flow of urine has been stopped on one side by the temporary compression of the renal artery the kidney of that side shows fully more carmine than its fellow. This condition would be reversed if the carmine in the cells were the result of absorption from a dilute urine.

4. In none of these cases does the stain show extensively in the glomeruli or capsule of Bowman when carmine dissolved by weak sodium hydroxid has been used. Even when the ureter has been obstructed and the kidney is deeply pigmented as contrasted with its fellow, the glomeruli do not show the pigment granules one would expect to find if the filtration through these structures had continued. If all the pigment found in the uriniferous tubules had come from the glomeruli and none from the epithelial cells, then the glomeruli should also be stained when their activity is stopped by obstruction to the outflow of urine from the kidney.

When ammonium carminate held in solution by glycerin is used the glomeruli show carmine granules, whether the ureter is obstructed or not. This solution has a greater diuretic action than any other substance used, and it is probably in more complete solution and more diffusible than the carmine dissolved by soda.

5. The glomeruli do not show a deposition of carmine granules, even when the animal is killed shortly after the injection of carmine dissolved by sodium hydroxid. In one experiment the kidney was excised four minutes after the injection of carmine and one minute after it appeared in the urine; in others after intervals of 10, 15 and 20 minutes, but in none of them have the glomeruli been stained as has been described with indigo carmine.

In conclusion it should be stated that these experiments merely indicate that pigments are excreted by a protoplasmic activity of the renal epithelium. They do not contend that none of the pigment is filtered through the glomeruli. On the other hand, when ammonium carminate is used the sections indicate that this is the case, and Starling's experiments with indigo carmine show the same thing. As stated before, we should bear in mind that both processes may operate at the same time.

The elimination of pigments by the kidney does not afford a method of determining positively and finally whether the rodded epithelium is excretive or absorptive in function, but the former seems the more probable. Of course, urea and the metabolites of the urine may be handled in a different way from foreign substances injected into the circulation. However, it seems improbable that the cells lining the uriniferous tubules are concerned exclusively in absorption, as has been contended recently.

DISCUSSION.

DR. E. R. LECOUNT, Chicago—I would like to ask if the arrangement of the pigment granules in the secretory cells of the convoluted epithelium was in rows, at right angles to the channel. We can recall that in various kinds of secretory epithelium it has been proven that there are intracellular passages. In the pancreas, liver cells and others there are pathways which lead into the channels. The renal epithelium is striated and the striations are at right angles to the tubules. I do not know that it has been proven that this is due to the existence of passageways, but it would be interesting to determine that point.

DR. W. S. CARTER, Galveston, Texas—I have not observed any such arrangement. The coarse pigment granules occur in great numbers near the lumen of the tubule, and where we have these very fine ones they are very evenly distributed through the protoplasm.

THE PHARMACOLOGIC ACTION OF DRUGS;

IS IT DETERMINED BY CHEMICAL STRUCTURE OR BY PHYSICAL CHARACTERS?*

ARTHUR R. CUSHNY, A.M., M.D.
Professor of Materia Medica and Therapeutics in the University of Michigan.
ANN ARBOR, MICH.

A close connection between therapeutics and chemistry has been recognized so long and has survived so many changes in each of these subjects that it was only natural that in the last half century the infant science of experimental pharmacology should renew the old alliance. Accordingly, soon after the idea of molecular structure and the use of structural formulæ were introduced in chemistry, the question was broached whether the effects of drugs in the organism could be co-ordinated with their molecular constitution. The answer has very generally been in the affirmative, and the view that there exists a direct relationship between chemical configuration and pharmacologic action has been supported by a number of important memoirs. Some sanguine advocates have even expressed the hope that with advancing knowledge of pharmacology the time may arrive when the action of a remedy will be deduced from its structure alone, and when the quest for new remedies will no longer be pursued in the haphazard way of the past, but with the definite object of forming a molecule of a certain structural arrangement, which will then necessarily possess the action desired.

Before considering how far this theory has proved to be correct, it may be well to examine what is meant by the structural formulæ which adorn so many pharmacologic treatises, but which I fear fail to enlighten as many readers as they repel. These may be regarded as a sort of shorthand statement of a series of reactions which the compound has been found to present; the structural formula, like a family tree, indicates the origin of the molecule, the products that may be expected from it when subjected to such processes as oxidation or reduction, and what compounds it is likely to

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

enter into combination with. On the other hand, the structural formula, again like a family tree, takes no account of the physical properties of the individual, such as the solubility, volatility, etc. For example, the formula of ethyl alcohol (CH_3CH_2OH) indicates its relationship to ethane (CH_3CH_3), acetic acid (CH_3COOH), etc., and suggests that it will tend to form combinations with acids, etc.; but if this substance were unknown and its formula only were before us, one could not infer with any certainty whether it would be soluble in water in any given proportion, or how volatile it would prove to be. The molecular structure may thus indicate the action of a substance in so far as that is determined by the combinations formed by the drug in the organism, but can give no clue to those effects which are due to its volatility, solubility or other physical properties. Now, it is obvious to every one that these influence the action of drugs very considerably; for example, the volatility of ether and chloroform determines largely their availability as anesthetics, while the less volatile nature of chloral and paraldehyd precludes their use for this purpose in man, but renders them more suitable than their more volatile relatives for use as hypnotics.

The importance of these physical factors has always received some recognition, for it has always been admitted that the relation between structure and action only holds as far as the physical characters of the bodies do not diverge too widely. Thus the lower alcohols all have a characteristic action on the central nervous system, which is lost as the molecule becomes more complex in the higher members of the series, and this has been explained by the molecule in the latter being absorbed less readily through its smaller solubility in the body fluids. But while admitting that the physical properties influence the results to some extent, it has been held that the real key to the action of remedies lies in their chemical affinities, that, for example, the change induced in the effects of methane (CH_4), by the substitution of a hydroxyl for a hydrogen atom is due rather to the chemical affinities of the hydroxyl than to the fact that the substance changes from a gas to a liquid. In recent years, however, the study of chemical structure has found a rival in the study of the physical characters; the properties of individual substances have begun to receive some attention as well as their relationships; and with this revival in interest the question has arisen as to the relative importance of the molecular constitution and of the physical characters of a substance in determining its pharmacologic action. In other words, a doubt has arisen whether the pharmacologic effects are due to the formation of chemical combinations in the tissues or to the presence of the drugs as uncombined foreign bodies in the cells and fluids. If chemical compounds are formed, then the molecular structure is the direct determining factor, though it may be modified by the physical characters, while, on the other hand, if no true chemical combinations are formed, the structure is of less immediate interest to the pharmacologist, and the physical characters ought to receive his chief attention, while the connection between the structure and the physical properties scarcely comes within his sphere of action.

A concrete example may illustrate the problem, and a simple one is offered by a comparison of the effects of methane (CH_4), which is practically inert, and of methyl alcohol (CH_3OH), which is a depressant to the central nervous system. It may be held that the OH of the alcohol permits of a combination being formed with protoplasm in the same way as with an acid, and that in the absence of OH in methane the latter is incapable of such a combination and therefore inert; or it may be suggested that the alcohol possesses some physical property, e. g., a lower volatility, which permits of its effecting some change in the cell without any chemical combination being formed, while methane is devoid of this physical property and inert. The question can be decided only by examining a large number of bodies and finding how far they support either view. For example, if it is found that no body homologous to methane is depressant and all the alcohols homologous with methyl alcohol resemble it in activity, there will be strong grounds for supposing that the hydroxyl in the methyl alcohol is the essential feature. On the other hand, if it is found that a large number of bodies possessing the physical characters of methyl alcohol, but without a hydroxyl group, are depressant, while those resembling methane in physical properties, but differing from it in structure are inert, the probability will be strong that the physical properties are the essential feature.

The time at my disposal is too short to allow of taking up all the work that has been done on this subject, and I think it will be more profitable to take up a few examples in which the action has been ascribed to one or the other factor.

One of the instances often quoted in support of the position that action is determined by structure is the large series of hypnotic bodies belonging to the aliphatic or open-chain series, including alcohol, ether, chloroform, chloral, paraldehyd, etc. Here is a series closely connected chemically and possessed of a characteristic action on the central nervous system. It is natural that it should be regarded as evidence in favor of the older view. It is true that the relationship proves only to be a very general one, and that whenever an attempt is made to apply the rule to individuals some exception is found to present itself. I need only cite the interesting experiments of Kionka[1] on the subject. He found that methane (CH_4), is devoid of narcotic action, while CH_3Cl has some effect. The presence of Cl appears to endow the molecule with activity, and further halogen substitution might be expected to augment this; on comparing CH_3Cl and $CHCl_3$, he found the latter four times more powerful. The inference would seem justified that CCl_4 would prove still more active; but as a matter of fact it is only half as depressant as $CHCl_3$. This result and numerous other similar divergences from what might have been expected from the older view have suggested that the depressant qualities of this series are not determined by their molecular structure, but by some physical factor which is present in a considerable proportion of the chemical group, but not in all of them. Professor Hans Meyer,[2] the originator of this view, ascribes the depressant action largely to their tendency to pass from watery solutions into fats and oils. Now, the cells in which these bodies tend to accumulate are peculiarly rich in lecithin and cholesterin (lipoids), and when a molecule of chloroform comes in contact with these cells it tends to leave the blood plasma and enter the lipoids. Its presence in the cells, however, deranges their delicate mechanism somewhat in the same way as a grain of sand may stop a watch, without any chemical combination having been formed. When chloroform is no longer inhaled and the blood becomes

1. Arch. internat. de Pharmacodyn. et de Ther., vii, 1900.
2. Arch. f. Exp. Path. u. Pharm., xlii, p. 109. Compare, also, Overton, Studien über die Narkose, Jena, Fischer, 1901.

free from it, the molecules in the nerve cells slowly return to the plasma, for though they are not so soluble in the latter as in the lipoids, they are not, of course, quite insoluble in it, and as those returning to the plasma are duly excreted in the lungs, more and more passes from the lipoids until these are finally capable of assuming their normal relation to the rest of the cell and consciousness returns.

In order to possess the hypnotic action associated with the methane series, a substance must thus be partially soluble in water or blood plasma and more soluble in the lipoids. In fact, a certain definite relation in its solubilities must exist, and in addition it must not act very powerfully on any other organ, otherwise its narcotic action will be obscured. This view is not unattended with difficulties, one of the most obvious of which is the fact that many substances share the physical properties of the narcotics without inducing their effects in the organism. Thus many substances of the benzol or aromatic series resemble the anesthetics in their relative solubility in water and lipoids, but fail to induce true narcosis. In some of them doubtless narcosis could be induced were it not for their affecting other organs. Meyer[3] has adduced one very telling argument in favor of his view in his investigation of the narcotic action of drugs at different temperatures and his comparisons of their relative solubility in water and oil at these temperatures. For example, he finds that the tendency of alcohol to pass from water to oil is almost twice as great at 30 C. as at 3 C., and in accord with this he found that it was about twice as depressant to tadpoles at 30 C. as at 3 C. On the other hand, less salicylamid passes into the oil from water at the higher temperature, and the narcotic action of this substance is correspondingly reduced. It seems quite impossible to account for this result on the older view of structural relationship, for this, of course, remains unchanged by the change in temperature.

In these cases the question is much complicated by the fact that the drugs have to be absorbed into the blood and distributed throughout the body and then taken up by the nerve cells; there is thus large opportunity for the interference of other factors than the relationship between the molecules and the nerve cells. A simpler process to follow is afforded by the local reactions, and one of these has been worked out in detail by Sternberg.[4] I refer to the characters of the bodies which have a sweet or bitter taste. Acid and alkaline tastes are, of course, not due to the similarity in structure of the acids on the one hand and of the alkalies on the other. but to the fact that acids in solution have a free hydrogen ion and alkalies a free hydroxyl ion; it is not similarity in molecular structure, then, but identity of ions that gives the identity of action here. Sternberg then confines his attention to sweet and bitter tasting substances and has obtained very striking results from his experiments, some of which may be mentioned here. The hydrocarbons are practically indifferent, but taste is conferred on them by the introduction of two or more OH groups, when the sense of sweetness follows. Thus glycol (CH_2OH-CH_2OH), glycerin ($CH_2OH.CHOH.CH_2OH$), erythritol ($CH_2OH(CHOH)_2CH_2OH$) and the succeeding members of the series are all sweet. The same result is attained if oxygen is added in the aldehydic form instead of in the form of hydroxyl. Thus biose (CH_2OH-CHO) is the first member of a sweet series, which may be followed up to dextrose if each C of the series has an OH attached to it. Even if one of the C atoms has no O attached to it the compound remains sweet, but if two C atoms are not oxygenated the taste is lost or changes to bitter. The oxygenated carbon atoms must, therefore, preponderate distinctly in bodies of this type which possess a sweet taste. That is, the sweetness is determined not by the presence of a definite group, but by the general character of the whole molecule; is there any physical character which is associated with such a molecule as Sternberg has defined as necessary to elicit the sensation of sweetness? Overton[5] has recently shown that the hydrocarbons are insoluble in water, but that as the HO groups increase in number they tend to give the molecule greater solubility in water and less in lipoids. Here, too, there must be a certain relative excess of the OH groups as compared with the non-oxygenated carbons; in fact, it seems possible to associate sweetness with a certain relative solubility in water and oils, although the subject requires much further investigation. The relationship between sweetness and this physical property is certainly suggestive.

A series of compounds which react very differently to living matter while practically indistinguishable by ordinary chemical reactions are the optical isomers. These have been studied of late years by Fischer,[6] who finds that the yeast cells and even the yeast ferments and emulsin can differentiate between the dextrorotary and levorotary isomeric sugars, while no ordinary chemical reagents select the one in preference to the other. Here again the property which determines the fate of these sugars does not seem to be associated with any one group in the molecule but to be determined by the character of the molecule as a whole, and this suggests that the selection of one isomer in preference to another by the ferments is due to the presence of some physical character, perhaps the rotation in one direction in the one, in the opposite in the other.[7] A similar selective action has been shown to occur in the higher animals as well as in the plants. I have recently been able to demonstrate a similar phenomenon in optically isomeric alkaloids. Thus levohyoscyamin proved to act about twelve times as strongly on the salivary glands as dextrohyoscyamin, although these two bodies can not be differentiated by ordinary chemical methods and would, therefore, be regarded as identical were it not for the different directions in which they rotate the ray of polarized light. It seems to me much more likely that the physical characteristic is the determining factor in this phenomenon than that the difference in configuration is the direct cause, although the physical factor undoubtedly rests on a structural difference ultimately. This can be determined, however, only by comparing the effects of other isomers on these organs.

Another set of reactions which appear to rest on a difference in physical properties rather than on chemical structure is offered by the behavior of the salts of the alkalies in the bowel. The class of saline cathartics can not be differentiated from the ordinary salts, such as the chlorids, iodids and nitrates, by any chemical feature possessed by the one group and not by the other, and it

6. Ztschr. f. Physiol. Chem., xxvi, p. 61.

7. That the direction of rotation influences the reactions is shown by the fact that these isomers may be separated by the use of reagents which are themselves possessed of rotary powers.

seems necessary to resort to some physical differentiation, although it is not possible to define exactly this physical property at present. Thus the sulphates, phosphates, tartrates, and citrates of the alkalies are all possessed of cathartic properties, while the chlorids, bromids, iodids and nitrates are practically devoid of this action, and it might be supposed that purgation is connected in some way with the bivalent or trivalent anion. This rule fails, however, in several instances, notably in the case of the monovalent cathartic fluorids and in some members of the acetic acid series. On examining this series Wallace[8] found that formates, acetates, propionates, butyrates, valerates and caproates were rapidly absorbed; the next member, the enanthylates, passed more slowly from the bowel, and the eighth of the series, the caprylates, resembled the sulphates in their behavior. On taking up a parallel series of bivalent salts, he found that the oxalates were absorbed with much greater difficulty than the higher members, the malonates and succinates. The constitution of these bodies thus gives no key to their effects, and it seems probable that a clue must be sought in their physical characters.

The theory that pharmacologic action is correlated with the formation of chemical combinations has received a new lease of life through the remarkable series of discoveries which have been made in regard to immunity and which form the foundation of Ehrlich's theory. It is too early to attempt a discussion of the physical properties which may underlie these processes, but it is to be remarked that in the case of one hemolysin whose chemical and physical properties are known, the activity appears to be determined by the solubility co-efficient rather than by its power of chemical combination proper. I refer to the observations of Ransom[9] and Hedon,[10] which render it probable that the destruction of the red corpuscles by saponin is due to the solubility of the poison in the lipoids, and that the antihemolytic effect of blood serum in this case is the result of the presence of lipoids in the serum. Somewhat similar results have been obtained with some of the bacterial lysins,[11] and it seems possible that conditions of solubility rather than true chemical combination may prove to be the explanation of the vagaries of the intermediate body. It is a well-known fact that certain drugs act only in the presence of other bodies which are in themselves inert, but which tend to facilitate the solution of the active principles. For example, the active principles of the vegetable cathartics often prove less satisfactory when given in a pure form than when mixed with the inert bodies with which they are found in Nature.

Full justice to this question could only be done in a much more extended paper than I am able to lay before you to-day. For though the question has arisen in its present form only in the last few years, the facts bearing on it are so numerous that they will occupy much time and many minds in classifying them. I shall be satisfied if I suggest to you that the time-honored view that chemical structure determines pharmacologic effect is once more on its trial, and that many facts which can be brought into accord with it only with a certain effort can be explained more satisfactorily by supposing that structure is only the ultimate fact, and that the physical factors depending on structure are the immediate determinants of the action in the organism. On the other hand, there is no reason to doubt that many of the reactions of the living organism to chemical agents are the result of actual chemical combinations formed between them and the living substance.

THE PHARMACOLOGIC ACTION OF DRUGS;

ITS RELATION TO THEIR THERAPEUTIC INDICATIONS.*

MAURICE VEJUX-TYRODE, M.D.
Instructor in Pharmacology, Harvard Medical School.
BOSTON.

The relation between the pharmacologic action of drugs and their therapeutic indications can best be shown after we have made a brief sketch of their history. From the earliest times to the present the use of drugs has been mainly derived from past experience. A system in which their use is based on past experiences which have not been carefully observed or controlled, as has been the case up to within a very few years, is called empirical therapeutics. A system in which the use of drugs is deduced from past experiences, which have been carefully controlled by scientific methods, is called rational therapeutics.

In the old days of Babylon when there were no physicians, the sick were exposed on the public ways so that they might converse with passers-by who perchance might have had the same ailment and who possibly could suggest a remedy. A similar custom prevailed among the Egyptians, who recorded on tablets in the temples the names of the remedies which had been found useful in certain ailments in order that they might be administered to persons suffering from these ailments. It is said that Hippocrates drew much of his therapeutic knowledge from such tablets in the temples on the Island of Cos.

Although various metals and salts were known to the old Egyptians, they relied almost wholly on drugs of botanical origin. Hippocrates, who lived about 460 B. C., based his therapeutics on the theory that the human body is composed of four humors—black bile, yellow bile, blood and phlegm, and that various diseases arose from the disproportion between these elements. He said that vinegar is diuretic and that its beneficial effects are due to its properties of dissolving the excess of black bile and of converting it into phlegm. He treated most diseases by emesis and cartharsis and used as emetics black and white hellebore, and as purgatives these, in addition to mezereum, rhamnus, elaterium, colocynth, scammory and aloes. As diuretics he used baths, wine, garlic, onions, leeks, cucumbers, celery and other strong-smelling substances and cantharides, and as narcotics he used opium and atropa mandragora. Externally he used a few metallic salts.

For several hundred years Hippocrates' successors followed practically the same therapeutics. Occasionally one advised mild treatment with but little bleeding, while another brought into vogue energetic treatment with profuse bleeding and purging and the use of drugs in large doses.

During the first century of the christian era, Dioscorides wrote a book in which he described all substances having medicinal value and named the subject materia medica. He divided the book into three groups devoted,

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

respectively, to drugs of animal, vegetable and mineral origin. This work is of importance, as it was used as the standard on this subject as late as the sixteenth century.

Galen, who lived in the second century, considered that the body was composed of fire, air, water and earth; that it possessed two of the four "proprieties," heat, cold, wet and dry, and that drugs act by removing the excess of one or more of these "proprieties." Like Dioscorides, he attributed to every drug two of these "proprieties" to a varying degree. Thus he considered pepper hot to the fourth degree and mezerum cold to the first degree. He considered astringent and salty substances hot, bitter substances dry, and acid substances cold. He treated all diseases, whether hot or cold, wet or dry, according to the axiom *contraria, contrariis curantur.*

From the fifth to the twelfth century the Arabs monopolized the field of medicine and science. They followed Galen and Aristotle closely, but introduced a few new drugs. Among these were camphor and the milder purgatives, such as manna, senna, rhubarb, tamarind and cassia. Muriate of mercury, which they used for scabies; orpiment, which they used as an injection in dysentery, and niter internally as a diuretic were a few of the metallic compounds used.

After the Arabians came the German, French and English alchemists, among whom were Roger Bacon, who prepared gun powder; Arnould de Villeneuve, who prepared alcohol and turpentine, and Basil Valentine, the German monk, who, in the fifteenth century, introduced antimony into medicine. Valentine was led to this step on account of an accidental observation which he made on swine which had eaten some antimony that he had thrown out of his laboratory window. The swine had been violently purged, but subsequently gained remarkably in weight.

The greatest of the alchemists was Paracelsus, who, in the sixteenth century, tried to utilize chemical knowlede in medicine and tried to overthrow the humor doctrines of Hippocrates and Galen. He believed that the living organism was composed of three elements: salt, mercury and sulphur; that its existence was maintained by chemical processes and fermentations, and that disease was due to a loss of balance between the three elements. His therapeutics was based on these assumptions and also on the theory that there was a specific for each disease. Syphilis, which in his time was raging through Europe, he combated very successfully with inunctions, fumigations and internal use of mercury. He used mercury with success in leprosy, dropsy and scabies. For this last-named disease he also used sulphur. As a purgative he used precipitated mercury. Unfortunately, he used drugs on account of their resemblance to certain organs—lemon, for example, for heart disease because it had roughly the shape of a heart, and blood root for blood disease because it was red. At the end of the sixteenth century, Van Helmont, who followed the principles of Paracelsus, completed the downfall of the Galenic humor doctrines and of the therapeutics based on it.

It was about this period that cinchona, which had been used for a long time by the Indians in the treatment of malaria, was imported from Peru and recommended for the treatment of intermittent fever because of the cure it had produced on the vice-queen of Peru. It was used in fevers of other varieties and, in fact, in almost all diseases. Lobelia and sarsaparilla, which were used by the Indians for syphilis, were also introduced at this period and were used by those who were opposed to mercury. Ipecacuanha was imported from Brazil, but was used mainly by charlatans until it was successfully administered for dysentery to the French Crown Prince. It then received universal application. In 1640, Parkinson, in his work on botany, described digitalis, and recommended its use internally for epilepsy and externally for gout. It was not until almost a hundred years later that Withering discovered its diuretic and cardiac action and recommended its use in dropsy where the heart is weak.

From the time of Hippocrates to the nineteenth century a number of new drugs were added to the materia medica. The drugs used in different diseases were often changed. New diseases were treated with both old and new drugs. Every now and then a specific was declared for a certain disease, but it was soon discarded for another. After many systems of therapeutics based on sophistry had passed through the history of the world, physicians used drugs more or less according to their own experiences. Practically all of them differed in their opinion concerning the value of a drug in certain diseases.

In ancient Greece and Rome after energetic treatments had been in vogue for a time a reaction took place, and only small doses and mild measures were used. In the same manner after a period of energetic treatment with heroic doses of drugs from the time of Paracelsus to the end of the eighteenth century a reaction took place in the establishment of homeopathy with its infinitesimal doses. After making very imperfect observations the founder of homeopathy, Hahnemann, came to the unwarranted conclusions that drugs had opposite actions in small and large doses; that they acquired mystical curative power by unlimited dilutions; that symptoms alone should be treated regardless of the cause of diseases, and that these symptoms should be treated by a drug which produced the same symptoms in large doses.

Unfortunately, this whole system was based on a fallacy. Drugs do not necessarily produce in small doses effects opposite to those which they produce in large doses and can not possess any action whatsoever in extreme dilution, and, further, so little was known accurately about drugs at that time that often very erroneous actions were attributed to them. Homeopathy had, however, a practical success, according to statistics. This is not astonishing in view of the fact that its followers employed the best possible hygienic measures, better even than those used in the other schools. By the too heroic administrations of drugs without proper knowledge of their actions the end of the patient was often hastened or at least recovery was often impeded, so it is quite easy to see the reason for the apparent success of homeopathy at that time, as it was a system which really consisted in administering no drug at all, and thus permitted Nature to cure when favored by good hygienic measures.

Pharmacology remained behind some of the other branches of medicine because the methods of observation used to study the action of drugs were entirely wrong. The ancients as well as the empiricists of the middle age could make no headway in pharmacology on account of their inaccurate methods of observations. When a person recovered from a disease after the use of a drug they attributed the recovery to the use of the drug without further attempts to find whether or not this was

really so or whether the use of the drug and the recovery were merely two sequent events.

The theory of obtaining knowledge by practical experimentation is certainly a good one, but observations must be made and conclusions drawn with the greatest caution. When a drug is administered to a patient and he recovers from the disease the question arises whether or not the recovery is due to the drug. Good clinicians in hospitals have tried salicylates in rheumatism in a series of cases and have come to the conclusion that they have marked action. Other equally good clinicians can not see any good effects whatever. This discrepancy probably comes from the fact that those reporting good results observed a series of cases the majority of which had the disease mildly while the others observed it in patients who had the disease severely. The errors of the clinical experimental method can to a certain extent be overcome when the action of the drug is observed on thousands of patients by a large number of physicians. The good effect of mercury in syphilis which has been attested by its action in a very large number of cases over a period of centuries is even now thrown into grave doubts by a number of syphilographers who claim equally good results without its use.

Another source of error in the study of drugs has been in the use of crude preparations. These contain very variable quantities of active substances, sometimes none at all when the active substances are easily decomposed. A crude preparation sometimes contains two substances which are antidotes for each other, so that its action may depend on the ratio of each substance present.

If the methods so far described for ascertaining the action of a drug and its value in disease are so unreliable, what can, then, be done to raise the efficacy of therapeutics? The development of chemistry and physiology has helped to solve this question. In large part through the influence of Bacon's teaching of the accurate method of experimentation and of accurate deduction, physics was developed and the mystic art of alchemy was gradually transformed into the exact science of chemistry. As soon as chemistry was placed on an accurate footing it took enormous strides. Soon numbers of new compounds were found and analyzed by new and accurate methods, so that at the beginning of the nineteenth century the body to which opium chiefly owed its activity was isolated. The isolation of morphin from opium by Seturner in 1816 was followed by the isolation of quinin from cinchona bark by Pelletier in 1820, the isolation of aconitin from aconitum by Brandes, 1821, the isolation of strychnin from nux vomica by Pelletier in 1818, and the isolation of atropin from belladonna by Brandes in 1823. By administering these pure active principles to animals and carefully studying their action when other influences were excluded the science of experimental pharmacology was developed. It was by this method that Morton by experiments on mice and on himself discovered the narcotic properties of ether and introduced it into surgical practice; that Schmiedeberg discovered and studied the active principle of poisonous mushrooms and taught us its antidote by which many lives have been saved. It was by this method that the chemist Pasteur discovered the cure for rabies and Roux the specific for diphtheria. Countless numbers of drugs could be enumerated whose beneficial influence in therapeutics was derived from a careful and accurate study of their pharmacologic action.

Knowing the exact action of a drug in health, how shall we apply this knowledge in disease? Pathologic physiology teaches us that disease is due either to the abnormal increase, decrease or arrest of a function from some cause or causes. Naturally, our first thought is that drugs should be directed when possible against the cause of a disease. Examples of this are the use of quinin in malaria and the use of antitoxin in diphtheria. This method is practical, however, in but a very limited number of diseases. We do not know the cause of many diseases, and but few drugs have been found to act on the cause of disease. Even if we could apply drugs to the cause of every disease, we could not have a perfect system of therapeutics, for decrease in certain functions may have been produced which would remain in spite of the removal of the cause of the disease. As the action of a drug consists only in increasing or decreasing functions, our main use of drugs consists in increasing functions which are abnormally decreased and decreasing functions which are abnormally increased.

But like all new sciences, during its infancy pharmacology received opposition. Some clinicians objected to therapeutics based on scientific experiments, and still advocated the old empirical system. Nowadays, however, there is not a good clinician who does not realize not only the usefulness but the indispensability of an accurate knowledge of the action of drugs in treating diseases. In former times physicians would have considered it sufficient to know that morphin relieves pain and produces sleep. We know now that we could not use this drug to best advantage and with safety without knowing something of its other properties which have been learned by scientific experiments. Thus in using morphin to relieve pain in pneumonia, asphyxiation might be hastened by a physician who does not know that morphin depresses the respiratory center. Again, a case of morphin poisoning can not be properly treated without a knowledge of the fact that morphin is excreted in very large part by the stomach for hours even after its subcutaneous administration. Knowing this fact, the stomach should be washed out repeatedly at stated intervals in order to remove the morphin which has been excreted before it is reabsorbed. Many other examples could be given to show that a superficial knowledge of drugs acquired from clinical experience alone is not only not productive of best results in therapeutics, but that it may even be dangerous.

Realizing this fact, the best clinicians the world over now try to base their therapeutics on experimental pharmacology. There are, unfortunately, still a few cases where we are obliged to use drugs empirically. When we do use them in this manner we should know all that could be learned through scientific research concerning the action of these drugs in order to avoid undesirable results.

The general anesthetics, ether and chloroform, are absorbed into the blood according to the laws of partial tension. The blood absorbs these from the air of the alveoli until it contains the same concentration. On the other hand, the anesthetic passes back from the blood into the air of the alveoli as soon as the concentration in the latter is decreased. The intensity of action of the anesthetics is not dependent on the total amount of anesthetics taken but on their concentration in the blood at a given time. Not very seldom death occurs during anesthesia from ignorance of these facts by administering a small amount of an anesthetic, but in a too concentrated form. None of the anesthetics, including ether, has ever been shown to have a direct stimulant action on the heart. On the contrary, they all depress

this organ when given in sufficient doses. This fact makes obvious the undesirability of the use of ether subcutaneously in collapse, and especially in collapse following ether or chloroform anesthesia.

Experiments show that chloral and its allies have marked depressant effect on the circulation and respiration, while urethane and paraldehyd do not have this marked depressant effect; in fact, urethane even stimulates respiration. This indicates to us the use of urethane and paraldehyd instead of chloral when the circulation and respiration are weak. Chloral, which is more powerful than the others, still has its usefulness in cases without weakness of respiration or circulation where a powerful hypnotic is required.

Ever since antiseptics were first discovered much labor has been spent in trying to find an antiseptic which would kill disease-producing organisms in the circulation. Benzosol, carbolic acid and formaldehyd have been recommended for pyemia and general tuberculosis. Experiments have failed to show any substance which can be placed in the blood in great enough concentration to kill bacteria there without injuring or killing the subject. The use of all such substances recommended up to the present time is certainly to be discouraged because not only do we not attain our end, but decrease the vitality of the patient with strong protoplasmic poisons and, therefore, hasten his death. There is one drug, however, which probably destroys an animal parasite in the blood, i. e., quinin in malaria. This is possible because of the great selectiveness which quinin has for the lower forms of protoplasm.

Apomorphin has been advised as a narcotic in the treatment of alcoholismus. It can easily be shown by experiments that apomorphin does not have any narcotic properties whatsoever except just before it produces death. Its beneficial action in cases of alcoholismus can be explained by its emetic action. By producing nausea it brings about a disgust for alcoholic beverages.

In former times a large number of drugs, including calomel and podophyllin, were used as cholagogues, i. e., to increase biliary secretion. Recent experiments have shown direct cholagogue effects to be produced by bile alone. The other so-called cholagogues are merely cathartics, and what good effects they produce can all be explained by their purgative action.

Digitalis is one of the most useful, but at the same time, most misused of drugs. Many physicians ignore the double action of digitalis on the heart, i. e., the action on the inhibitory apparatus and that on the heart muscle directly. The main indication for digitalis in medicine is based on its power of increasing the force of the heart contraction. The results desired in cardiac uncompensation, an increase in the force of the heart and disappearance of dropsy, may be obtained with little or no diminution in the rate of the heart beat. On the other hand, decrease in the rate may occur without a sufficient increase in the force of the heart. In determining the dose of digitalis in a given case of cardiac uncompensation we must not be guided by the effect on the rate of the pulse alone, but especially by the effect on the force of the pulse, by the disappearance of the edema and by the increase in diuresis. Since the action of digitalis is to increase the force of the heart, its administration in a fully compensated heart is not indicated because it can then only uselessly overwork the heart. Since the action of the various members of the digitalis group, such as strophanthus, squills and convallaria, is, in the main, the same as that of digitalis, these can be used interchangeably with the latter.

Strychnin slows the heart by stimulation of the vagus and constricts the peripheral vessels by action on the vasomotor centrally and peripherally, but it does not stimulate the motor ganglia nor the muscle of the heart. These facts suggest a different use for strychnin than for digitalis. Strychnin can be used only to lower the rate of the pulse in tachycardia or to raise blood pressure in collapse, but good results can not be expected when we wish to increase the power of contraction of the heart directly. It should be used with care in degenerated hearts and vessels for fear of straining the former and rupturing the latter by the increased blood pressure incident to the constriction of the peripheral vessels.

For ages patients have been advised to frequent springs and spas for the cure of almost every disease. It is only comparatively recently that we have understood the modus operandi of this treatment and the source of benefit when obtained. Mystical curative power was formerly attributed to baths. We know now that neither water nor salts are absorbed through the unbroken skin, therefore baths can only have local effect on the skin, which is an irritant one, capable of producing reflex stimulation of circulation, respiration and consequently of metabolism. The ingestion of large quantities of water with salts produces an increase in metabolism by the salt action after absorption. On account of this increase in metabolism patients with almost any chronic disease are temporarily benefited. Furthermore, on account of the fact that salts and alkalies have the power of dissolving mucus, mineral waters containing these can benefit patients with catarrhs of the stomach and intestines by dissolving the mucus which is adherent to the walls. It is obvious that the same good results might be obtained at home by baths and by drinking water to which various salts had been added if we had not in the spas the additional action of the psychic influence of change of scenery, pleasant surroundings and careful régime.

[The discussion on the papers of Drs. Cushny, Tyrode and Sollmann will follow the paper of Dr. Sollmann next week.]

NON-ABSORBENT GAUZE:

THE PROPER MATERIAL FOR TAMPONADES IN SURGICAL AND OBSTETRIC HEMORRHAGES; A PRELIMINARY PAPER.*

RUDOLPH WIESER HOLMES, M.D.

Instructor in Obstetrics and Gynecology, Rush Medical College; Obstetrician to the Passavant Memorial Hospital, and Associate Obstetrician to the Chicago Lying-in Hospital.

CHICAGO.

In presenting the subject of non-absorbent gauze for your consideration I am not offering a new topic for discussion; non-absorbent gauze takes its origin contemporaneously with the antiseptic dressings of Lister. Lister's[1] earlier dressings were distinctly non-absorbent; the manner of their production secured it, for muslin was soaked in a heated mixture of paraffin 16 parts, resin 4 parts and carbolic acid crystal 1 part; while still warm the excess of the compound was wrung out. Lister[2]

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

2. Lister, J.: Edinburgh Med. Jour., p. 147, 1871.

shortly thereafter even suggested an 8 per cent. carbolic gauze made in the same manner. The paraffin counteracted the adhesiveness of the resin, and together they precluded a capillarity in gauzes thus treated. The faults of this carbolized gauze were early recognized and were its non-absorbence and its tendency to cake into a solid mass. In turn, Lister[2] experimented with corrosive sublimate and cyanid of mercury; the former, he found, combined with the discharges (pus and blood), being precipitated as an albumin-mercury chlorid, which did not have the antiseptic power of the bichlorid. By suspending the albumin-mercury chlorid in blood serum he secured a gauze which was "harsh mechanically and was not very absorbent (a serious defect)." To overcome these defects he tried a combination of the chlorids of ammonia and mercury (sal-alum-broth), the ammonia salt preventing the precipitation of the mercuric salt in the presence of albumin, but not inhibiting capillarity. The cyanid of mercury was too irritating for clinical use. Thereafter, surgical supply manufacturers used their skill in developing a true absorbent gauze.

My purpose in presenting these elementary facts is to show not Lister's endeavor to secure an ideal antiseptic gauze (his prime motive), but his endeavor to find an antiseptic gauze which was truly absorbent. His contemporaries, old and young, have kept his second purpose constantly in mind, and the original gauzes which were truly non-absorbent have been relegated to unmerited oblivion. In the early antiseptic days wound secretions were frequent, so an absorbent gauze was the desideratum of all surgeons; to-day, discharging wounds are seldom met, so the same necessity in all cases for a gauze with a marked capillarity does not exist as in former decades. To say the least, it does seem inconsistent for surgeons to require the same gauze for purposes of drainage as for packing in hemorrhage.

About a year ago R. H. M. Dawbarn of New York, in a personal communication, wrote me of the value of non-absorbent gauze in hemorrhages incident to surgical operations, and suggested that, in his opinion, it had as positive indications in obstetric uterovaginal tamponades as in surgical procedures; that for ten years he had repeatedly advised its use in various contributions on surgical subjects. The burden of my reply was that one of the physiologic functions of the puerperal uterus was to bleed for a variable period; therefore, if a gauze pack were introduced into the uterus it should be of such nature that it would not prohibit the normal drainage of that organ. Incited by his suggestion, I asked Johnson and Johnson to send me samples of plain non-absorbent gauze, with which I made some tests as to its action; the results of my experimentation, which will be epitomized later, have convinced me that when properly prepared its use is as clearly indicated in obstetrics as in surgical work. The one case in which I felt it was expedient to tampon since I began my investigation fully corroborated my tests; this case was one of severe hemorrhage following the manual removal of the placenta in a four months' criminal abortion.

The manufacture of non-absorbent gauze is practically a step short of the production of absorbent gauze; the raw cotton is thoroughly cleansed, then through devious treatments the individual fibers are gathered into threads, and the threads woven into the desired gauze. If the gauze is to be rendered absorbent it is boiled in a strong alkaline solution in order to remove the vegetable oil. The difference between the above non-absorbent gauze and commercial cheesecloth lies in the fact that cheesecloth is treated with a "sizing," such as albumin, preparations of zinc, clay, etc. The sizing increases the weight of the product, and also permits the utilizing of certain waste materials. In certain crude experiments as to the action of non-absorbent gauze I found these facts:

1. If the loose gauze be placed in a vessel containing a colored solution it floats; only that portion of the gauze brought into direct contact with the water is stained; no capillarity is observed. If the gauze be tightly rolled into a ball the same result occurs.

2. If the gauze be slightly dampened capillarity manifests itself after a protracted period; in one instance the solution passed over the rim of the vessel and down the dependent portion at the end of six hours. In a like test with absorbent gauze the water dropped in about a half hour.

3. If the gauze be thoroughly saturated with water and then subjected to the test, capillarity manifested itself shortly after a like treatment of absorbent gauze; when capillarity was thoroughly established the drops from the non-absorbent gauze fell more rapidly than from the other; the difference in capillarity may be ascribed, perhaps, to altered physical conditions—the size of the thread, more probably the size of the mesh, and the solidity of the wicking used, or if the mesh be filled with droplets of water "osmosis," if you please, may be the determining factor in producing a siphonage.

As a result of my tests I would hazard the statement that moist non-absorbent gauze has one-sixth to one-tenth the capillarity for water of the plain absorbent gauze. Some may raise the question, is a test with water applicable to the physical properties of blood? I maintain these tests are only illustrative; but I am confident that the two types of gauzes have relatively the same capillarity when considered with blood. Finding that the unprepared gauze under certain circumstances of moisture, or other physical conditions, may have a capillarity, has suggested to me that for certain restricted purposes in pure surgical work a gauze should be prepared which has no absorbency whatever; with this object in view I have considered the advisability of treating gauze with some substance which would attain this object. To be effective this substance should promote coagulation, or at least not delay it. As Lister's gauze was non-absorbent, from the method used in its preparation, I first thought of paraffin, so had some made. It produces a fine-looking gauze, soft in texture, but with difficulty takes up water or antiseptics within its substance. The chief objection to its use is that paraffin delays coagulation, so it is not an ideal substance for the purpose. As Pagenstecher[3] has had signal success with celluloid yarn for suture material, I turned to it as the next possibility. Perhaps the same objection obtains as against paraffin. These two substances do not agglutinate the fibers of the thread, as is evidenced by the samples before you; it is known that a rough substance, especially one with fine projecting filaments, accelerates coagulation, so what is gained by non-absorbency only may be lost by these two substances delaying clottage, which may be a serious defect. By incorporating an approved antiseptic in the fluid paraffin or celluloid, gauzes thus prepared may be made thoroughly bactericidal. O. Schaeffer[4] suggests, and uses, for post-partum uterovaginal tamponades a gauze impregnated with gutta percha; his paper was noted by me at the time of its publication, but his recommendation did not

3. Pagenstecher, J.: Phila. Med. Jour., p. 351. Feb. 10. 1900.
4. Schaeffer, O.: Münch. med. Woch., p. 945, Oct. 6, 1896.

make a particular impression on me; his plan of putting an absorbent strip of gauze against the bleeding site (e. g., the placental site), and then packing about this strip the gutta-percha gauze, did not seem feasible to me. Non-absorbent gauze treated with gelatin in many respects would be an ideal solution of the difficulty; gelatin, whether used by hypodermoclysis, by mouth, or by rectum, promotes coagulation; when applied directly to the bleeding surface it is more certainly effective. I have used gelatin absorbent gauze in my tamponades several times with positive results. Gelatin gauze can hardly be a marketable product on account of its great liability to germ contamination, as it is a good culture medium; again, the frequent German reports of tetanus following the hypodermatic use of gelatin demand that it be sterilized with especial care. It has been recently stated that the hemostatic property of gelatin is dependent largely, if not exclusively, on the calcium chlorid contained in it. If calcium chlorid is the hemostatic principle of gelatin it would be far more safe and rational to impregnate gauze with a weak solution of the salt, one to 200 or 500. There is one adverse factor in regard to calcium chlorid gauze for uterine tamponades, namely, the gauze must be both aseptic and antiseptic if it is to be left in place twenty-four to thirty-six hours; it may be a difficult proposition to get a good antiseptic which will not decompose in the presence of the calcium. In parenthesis I might state that the usual gauzes impregnated with antiseptics have not the capillarity of plain gauze. Hall[5] maintains this; Vignard[6] claims iodoform gauze has only one-fifth the absorbency of plain gauze; the users of medicated gauze do not get the full drainage they anticipate.

INDICATIONS FOR THE USE OF NON-ABSORBENT GAUZE.

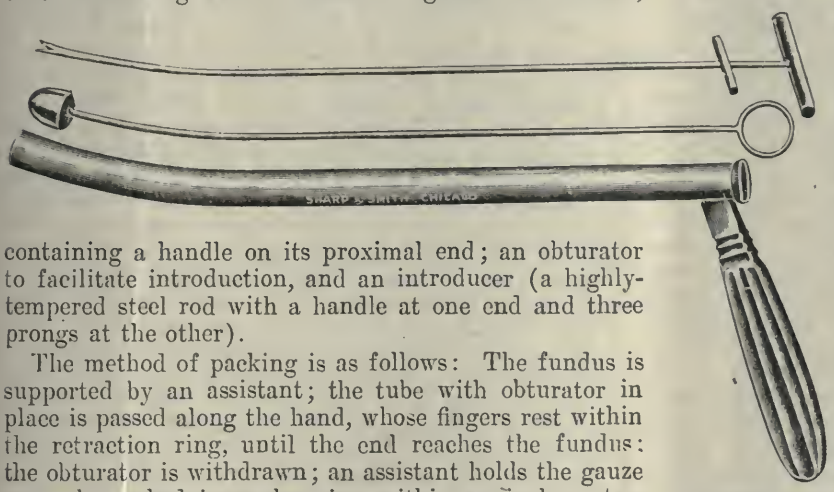
When drainage is indicated in the abdominal, pelvic, thoracic, pus cavities, etc., there is no room for doubt that the gauze must be absorbent to the greatest degree. in stating this I make no asseveration as to the merits of gauze drains. The routine dressing for clean, dry wounds and surfaces, I am equally convinced, should be covered with the usual hygroscopic materials. *Per contra,* in cases of hemorrhage where it is impossible to catch the bleeding vessels with forceps or inexpedient at the moment to ligate, and in parenchymatous oozing, a gauze should be applied which possesses a minimum degree of capillarity, or one in which absorbency is entirely absent. A few illustrative instances will be sufficient; the rapid extirpation of the carcinomatous breast with the axillary glands with one sweep of the knife, as practiced by N. Senn; no clamps are applied until the breast is disposed of; here firm compression, not capillarity, is required. Non-absorbent gauze will find a ready use in that bloody operation of removing the upper maxillary bone, etc. In these cases, as well as in alarming hemorrhage from ruptured vessels in the course of difficult laparotomies, with concomitant shock, the blood absorbed by the usual gauze may be of such amount as to seriously jeopardize the life of the patient; by packing with a non-absorbent gauze some ounces of blood may be saved to the patient which otherwise would be lost, and the danger point will be more safely tided over.

In the meager presentation of the surgical indications of non-absorbent gauze my only purpose is to introduce the subject to surgeons; it is for them to place the indications for the use of the several forms; for mere compression I believe an impervious, or at least dry, gauze is to be elected; where compression and a modicum of drainage is demanded untreated non-absorbent gauze will be preferable.

OBSTETRIC INDICATIONS.

Antepartum.—The purpose of vaginal tamponades antepartum are fourfold: 1. To promote contractions. 2. To distend the vaginal vault, raise the uterus, and thus pull on the uterine arteries, acting as a tourniquet (Tweedy[7]). 3. To produce a compress against the bleeding surface (placenta previa). 4. To retain the effused blood so clotting may occur and thrombosis take place. The first three purposes will be as certainly produced by absorbent as non-absorbent gauze; their action is purely mechanical. As to the fourth, some may question which gauze is more effective; but either will act only as a mechanical stimulant to coagulation. I imagine that those who will defend the former will maintain that as soon as the serum is extruded from the clot it is absorbed by the gauze, thereby promoting further clotting. Coagulation is not an instantaneous process, it takes time; during the interval which must elapse absorbent gauze becomes saturated with blood, it has literally sapped the blood from the vessels; *per contra,* if non-absorbent gauze be used an efficient dam is pressed against the source of the bleeding, so only a minimum amount of blood escapes. Therefore, I would suggest that non-absorbent gauze should be used as the routine tampon material in all antepartum work where plugging is indicated, as in abortions, hydatidiform mole, placenta previa, etc.

Postpartum.—The virtues which we attribute to the antepartum vaginal tampon apply with equal force to the postpartum uterovaginal pack; I am positive that the most certain means of arresting postpartum hemorrhage lie in the timely use of thorough tamponades. I do not hold that tampons come into direct concurrence with massage through the abdomen, intrauterine compression, Breisky's bimanual compression, ergot, hot douche, and the other more or less certain means of securing contraction and coagulation, but I do maintain that all these should be held as tentative measures; when their uncertainty is manifested temporizing measures should be discarded and the gauze applied. To be sure, in very exceptional cases it will fail, but failure would be more glaring consequent to other methods of arresting bleeding. Chrobak[8] states that the tampon failed three times in twenty-seven cases of atony after delivery of the placenta.



I would place the indications for the uterovaginal tamponade under these headings: 1. Atony. 2. Lacerations of the parturient canal (especially of the cervix) under such circumstances which preclude the delay incident to suturing the tears; in incomplete rupture of the uterus, and exceptionally in complete rupture. 3. Hemophilia (blood dyscrasia). 4. As a prophylactic against hemorrhage, as after severe operative deliveries; rapid delivery may be the cause of atony postpartum; the introduction of the tampon secures firm contractions. and prevents hemorrhage; the quicker the woman is returned to bed the better it is for her; this is especially the case in placenta previa. 5. As a prophylactic against infection; midwife cases, examinations by questionable hands, especially futile attempts at operative delivery; after manual delivery of the adherent or retained placenta.

5. Hall: Boston Med. and Surg. Jour., p. 518, vol. 137, 1897.
6. Vignard: Bulletin Med., Paris, No. 21, 1902.
7. Tweedy: British Med. Jour., p. 1445, vol. I, 1898.
8. Chrobak: Wiener klin. Woch., Sept. 18, 1902.

In using the tampon as a prophylactic against infection I most certainly would not recommend a non absorbent gauze; here a gauze with good drainage power must be used; it should be impregnated with a powerful antiseptic which at the same time is innocuous to the human organism; thus far I have found no chemical which so fully meets the indication as chinosol. In all the other conditions warranting the tampon I would use the non-absorbent gauze medicated with chinosol. It is frankly debatable if it is proper to employ a gauze charged with a substance which prohibits all capillarity, of a nature as I have already described. In blood dyscrasias I am positive gelatin gauze holds first rank; perhaps calcium chlorid in combination with a stable antiseptic may vie with it in efficacy.

TECHNIC OF INTRODUCTION.

I shall not dwell on the methods of Dührssen, Schauta and others who vary the method of packing by using the hand alone, the hand and dressing forceps, or the specula, vulsella and dressing forceps; they have been repeatedly described, and in proper surroundings merit their use. I would like to call attention again to the packer I exhibited to the Chicago Gynecological Society,[9] November, 1901. This instrument is a modification of some now in use, altered to meet the conditions of the parturient uterus. It consists of three parts (see illustration): a properly curved tube twenty-eight centimeters long with a caliber of eighteen millimeters,

containing a handle on its proximal end; an obturator to facilitate introduction, and an introducer (a highly-tempered steel rod with a handle at one end and three prongs at the other).

The method of packing is as follows: The fundus is supported by an assistant; the tube with obturator in place is passed along the hand, whose fingers rest within the retraction ring, until the end reaches the fundus: the obturator is withdrawn; an assistant holds the gauze properly packed in a glass jar, within an inch or two of the proximal opening of the tube, an end is picked up with a forceps and passed within the tube; then the introducer pushes it through the tube; finally, with quick back and forward movements, the introducer catches the gauze near the distal end of the carrier and carries it into the uterus, and eventually into the vagina. As the gauze is pushed home, the hand in the vagina holding the tube is gently swayed from side to side, thus completely filling the parturient canal. As the gauze escapes from the tube it (the tube) is gently withdrawn—in fact, is pushed back by the escaping gauze. Since introducing this instrument I have packed the genital tract eighteen times for the various indications already briefly enumerated with uniform success, and am convinced it is the safest method for placing gauze within the uterus: 1. It is the only aseptic method, for the gauze does not come in contact with living tissues until it is in its bed. I do not except the method where specula, vulsella and dressing forceps are used. 2. It requires only one introduction of an instrument; the dressing forceps must enter the parturient tract at least thirty, if not sixty, times. 3. Further abrasion of the already scarified mucous membrane is absolutely obviated; rough gauze passing over the membrane will make additional denudations, and may dislodge clots which are forming. 4. One assistant only is necessary, although two are preferable; he may support the fundus and hold the jar of gauze at the proper place; by other methods two assistants are wellnigh indispensable. The only disadvantage I can imagine is that in a marked atony of the uterus the packing may not, perhaps, be as firmly applied, which I feel is a valid objection.

Finally, whatever method of introduction is used it is indispensable to have a properly prepared gauze, one which is aseptic and antiseptic, and is so placed in the container that it feeds out without any handling. The gauze should be at least ten yards long, one-half yard wide, folded into a strip about two inches broad with the free edge perfectly covered; this strip must be felted in the jar; under no circumstances must it be rolled up, then placed in the receptacle. At the present time no gauze suitable for obstetric tamponades is on the market.

387 North State Street.

9. Holmes, R. W.: Amer. Jour. of Obst., p. 245, February, 1902.

DISCUSSION.

Dr. Chas. S. Bacon, Chicago—The assumption that absorbent gauze is drainage is not in accord with facts. It is well known that a gauze packing is a packing and not a drain. Wicking should be used when a drain is wanted. The impregnation of gauze with hemostatic substances is much more important than the impregnation of gauze with something that makes it non-absorbent. The idea of mechanical compression of bleeding vessels of the uterus in postpartum hemorrhage is, I believe, a mistake. We can never pack the uterus so as to compress the bleeding vessels unless we have the contracting action of the uterus. Stimulation of the uterus to contraction is essential in postpartum hemorrhage. Whether that is done by gauze or by some other substance is immaterial. In some cases it is desirable to hasten the coagulability of the blood. That is particularly true in cases of dyscrasia where there is a slow coagulation of the blood; these are the most serious cases, and are not so extremely rare. It is important to have some hemostatic or coagulating action in these cases, and that is secured by the use of gelatin or other substance. Investigations in that line are desirable. There is an indication for gauze packing in postpartum hemorrhage, such as lacerations that are not controlled by sutures. These are lacerations in the lower uterine segment that for some reason can not well be repaired by suture. Here we must rely on the contraction of the upper segment of the uterus to furnish resistance to the tampon. There we get a certain amount of mechanic compression, but it is not the compression that would be obtained in a surgical cavity after all, and even in these cases gauze impregnated with some coagulating substance would be useful.

Dr. C. O. Thienhaus, Milwaukee—In general surgery also we sometimes encounter situations in which gauze capable of promptly arresting capillary hemorrhage would be of greatest value. About two years ago a man of about 80 years of age was suffering from a chronic catarrh of the antrum. After opening the supermaxillary cavity, I endeavored to remove a few polypus growths on the middle turbinate. A severe hemorrhage followed which I was unable to control by gauze packing. Adrenalin solution stopped the hemorrhage promptly. Experiments ought to be made with gauze impregnated with adrenalin or with gelatin. Naturally, the drug used must not show bad effects on the wound or on the welfare of the patient.

Dr. V. M. Showalter, Point Clear, Ala.—Tamponage in postpartum hemorrhage is impractical and unscientific, except when the circular artery is involved in the laceration. One never has time to get the packing outfit ready. Immediate aid must be rendered. I have done this work for many years. A number of my patients suffer from pernicious anemia, which in some cases is secondary to uncinariasis, and with the seventh or eighth deliveries I usually expect a postpartum hemorrhage, and I am seldom disappointed. I never yet had a case where I had time to use tamponade or anything else except my hand. It is fashionable in my section to have very large families.

Dr. Hugo Ehrenfest, St. Louis—Tamponade is one of the most effective and important therapeutic measures at our command in dealing with obstetric hemorrhages. In practice we meet two difficulties: (1) We can not get gauze fit for tamponade. (It would be a great advantage if such a gauze should be marketed.) (2) It is a difficult procedure in packing the uterus to not carry infection from the vulva into the uterus. Special specula have been devised to protect the gauze which is introduced into the uterus, but they are very large and bulky. The instrument presented by Dr. Holmes is a valuable one. It will enable us to pack the uterus under aseptic conditions, and it is not so bulky that it can not be carried in the ordinary bag.

Dr. Wm. P. Manton, Detroit—Postpartum hemorrhage should be divided into two classes. In the first a large amount of blood is poured out in so short a time that the obstetrician has not time in which to do anything. In those cases there is sometimes a paralysis of the uterine muscular fibers, and the patient succumbs before the obstetrician can render assistance. In the ordinary cases of postpartum bleeding the hemorrhage is not so severe, but the obstetrician must act promptly and pack the uterus, and so stop the hemorrhage. The irritation of the gauze undoubtedly also acts in promoting contractions of the uterus. In my opinion, the absorbent gauze answers every purpose, although I have not had an opportunity to use the non-absorbent material. The blood fills the interstices of the gauze and promotes coagulation. This the non-absorbent gauze can not do. Any obstetrician of skill can, in the ordinary case, pack the uterus so tightly that not a drop of blood will escape. I think the drainage of serum is an advantage, and I can not see where, in obstetric practice at least, the non-absorbent gauze would be better than the absorbent. When we want to get drainage through the gauze we must use the absorbent, and in this respect the absorbent gauze is superior to the other.

Dr. Seth C. Gordon, Portland, Me.—Prevention is far better than cure, and I believe that nine-tenths of all postpartum hemorrhages can be prevented if the obstetricians do what they should. When I was studying medicine one of the best teachers in any branch was Prof. E. R. Peaslee of New York. He said never to deliver a woman without having some one press the uterus down as the child was being born. After the child is delivered this pressure on the uterus should be continued until the obstetrician is ready to take charge of the placenta. If one follows this teaching one will have less postpartum hemorrhage; in fact, I believe it will be rare.

Dr. H. J. Stacey, Leavenworth, Kas.—Absorbent gauze pushed in the uterus does not act as a drain. The only effect is to assist coagulation. Does not packing with a non-absorbent gauze act more like a plug and allow a condition very similar to accidental hemorrhage to occur? The only procedure in packing that is of any value is the manual method, as there is no time in which to get all the various instruments ready, although in a slow hemorrhage they might be used to advantage. In obstetric work I think Dr. Holmes has a very doubtful field for his gauze and packer.

Dr. H. E. Pearse, Kansas City, Mo.—We sometimes find it absolutely necessary during an abdominal surgical operation to control hemorrhage by packing, although it is not perfect surgery. It is always a confession of defeat. The control of hemorrhage is not the only factor to be considered; there is the question of drainage, the hemostasis being perfect; and of infection. It is essential to use nothing but absolutely sterile gauze. I long ago discarded medicated gauze where plain sterile gauze would answer the purpose, as it usually does. I control simple venous oozing with plain gauze, although this will not control arterial hemorrhage. Iodoform gauze is better for that purpose, although alum water is also useful. When we have to deal with an infected surface it is advisable to use iodoform gauze. When gauze is needed only to control hemorrhage I believe I will try Dr. Holmes' non-absorbable gauze. In that limited field of non-infected surfaces with a bleeding vnat is arterial, it would be a very desirable procedure.

Dr. Rosa Wiss, Meridian, Miss.—By having a pair of sterile rubber gloves in my bag I once saved a woman's life. I was called suddenly to deliver her of her twelfth child and found her all alone. Spontaneous delivery was very rapid, and immediately following a stream of blood as large as my wrist poured from her uterus. I knew that if that flow continued for a few minutes the patient would die. I remembered that I had my gloves, so I put them on and introduced my hand into the uterus, keeping the other on the abdomen to make pressure. I kept them in that position until I succeeded in stopping the hemorrhage. I sat there in that position for two hours, but the woman came through all right, and is alive to-day.

Dr. Effa V. Davis, Chicago—I desire to speak in favor of the instrument shown to-day. We all draw our conclusions largely from our own experience, and in twelve years of active obstetric practice I have seen very few postpartum hemorrhages, consequently I have a great deal of confidence in prophylaxis. The packing of gauze is such a very difficult procedure that other things which are more easily done should be considered first. In prophylaxis, simply holding the uterus at the birth of the child is not always a sufficient safeguard. One source of hemorrhage is a long, tedious birth, causing inertia of the uterus. Chronic endometritis, leaving a partially adherent placenta, is often another element. If we think of these things before delivery they will be of service. It is unwise to keep the subject of packing the uterus too prominently before us and to the exclusion of all other things. The obstetric work of the world is not done by the expert obstetrician, but by the busy general practitioner, who can not carry all these instruments all the time. The introduction of gauze over an unclean vulva and unclean bedding is a matter not to be overlooked. It is a procedure to be looked on with a great deal of fear and trembling in the hands of the general practitioner, who is often so illy prepared to do obstetric work. Packing the uterus is not the only thing, nor the first thing to do. We still hear of deaths from puerperal sepsis, and puerperal sepsis following the postpartum hemorrhage is in many instances the element which produces a fatal result, as the anemic state of the patient leaves her in the poorest possible condition to resist infection.

Dr. Granville Ryan, Des Moines, Iowa—Dr. Davis' point is too often overlooked, i. e., the matter of packing the uterus without having everything sterile. I have had a number of very severe cases of postpartum hemorrhage, but I have never packed a uterus, nor have I lost a case, nor had an infection. I always have normal salt solution and plenty of sterile water. I douche with the normal salt solution just as quickly and as hot as it can be applied. In addition I give strychnin and stypticin hypodermically and perform hypodermoclysis if necessary. I am very careful to antisepticize my hands and the vulva, of course. My experience has been that we too often forget or neglect to look into the history of the case to ascertain whether or not the patient is a bleeder. It is very necessary that that should be done. And, above everything else, we owe it to our patients to have a complete armamentarium and be ready for any emergency.

Dr. V. M. Showalter, Point Clear, Ala.—The advocation of tamponade is unscientific in conception and impractical in application. I may not possess the obstetric skill of others, but I can recall, from memory, fifteen patients with postpartum hemorrhage in the last fifteen years, and, thanks to the painstaking instruction I received from my old preceptor,

Dr. Owen of Mobile, I have never lost a case. In the cases where the blood flows like water from a pump you have not time to do anything except to put one hand into the uterus and place the other on the abdomen to excite contraction of the uterus. I always have an abundance of sterile water and salt solution prepared. I have never yet had the privilege of testing the value of prophylaxis because, as a rule, I do not see my patient until within thirty minutes of the time when the child is born. I do not believe that any man can on purely scientific grounds prove that tamponade is practical.

Dr. R. W. Holmes—The discussion has been largely on the treatment of postpartum hemorrhage. No one feels more than I do the value of prophylaxis in this condition, but every text-book of to-day makes positive, sweeping statements that are far from being true. They say that prophylaxis can eradicate postpartum hemorrhage entirely. That is impossible. We all should have a standard as to what is a normal blood loss. A woman who loses six ounces or more of blood should be considered to have postpartum hemorrhage, which includes 10 per cent. of women at least; but, fortunately, it is only 1 in 200 in which the hemorrhage is of any moment; and only 1 dies in 1,000 or 2,000. But the profession must learn that postpartum hemorrhage is one of the most frequent complications of labor, far more frequent than the complications of the first and second stage. The Credé treatment is recommended after twenty minutes, but in 60 to 75 per cent. of the cases a Credé can not be done after twenty minutes because the placenta is already out of the uterus. Credé treatment means the forcible separation and expulsion of the placenta from the upper uterine segment. As to adrenalin, the manufacturers would not recommend its use in the uterus; one death is reported following its use; its internal administration does not concern us here. Saenger recommended that ferrotannin be used; it is both styptic and, to a small degree only, an escharotic. Glutol is another, and there are many more substances which promote clotting. Any one who has put a tampon in the postpartum uterus knows that there is a capillarity to the gauze. There is not entire stoppage of blood between the tampon and the mucous membrane, because after three or four hours the napkin becomes stained with serum, and when the tampon is removed it is usually saturated with blood. I distinctly said in my paper that I did not believe in putting in absolutely non-absorbent gauze. I said it should be moist, which produces a minimum amount of capillarity. The uterus contracts and forces the blood into the meshes of the gauze, and when capillarity is once started it goes on just the same as in the case of absorbent gauze, only more slowly. The subject of drainage is entirely without the scope of the paper. The day has gone by when the physician can go to an obstetric case not prepared for the work. He must have a complete armamentarium, and I am thoroughly in accord with King of Washington, who said at least fifteen years ago that any man who went to an obstetric case and did not have an armamentarium to meet the ordinary emergencies of labor should be held criminally liable. The day of the man midwife is past. There are too many of them; they should be wiped out. I think the time will come when the man who goes to an obstetric case with his forceps wrapped in the morning paper will be held incompetent to practice his profession. Any man able to do obstetric work should be able to tampon a uterus. The instrument I have presented offers the only means of tamponing the uterus quickly, and at the same time eliminates all possible sources of contamination from the gauze sliding over the vulva and vaginal mucous membrane. The last speaker voices the opinion of those who decried the tampon when Dührssen first introduced it; its adoption by practically all scientific obstetricians is sufficient attestation of its inestimable value.

Some Uses of Olive Oil.—Beside having value as a mild laxative and tonic for babies, olive oil may be found of service in dysentery, in severe diarrhea and in chronic catarrhal gastritis.—*Texas Medical News.*

DESTRUCTIVE STERILIZATION BY CATAPHORESIS OF CANCER OF THE UTERINE CERVIX.*

G. BETTON MASSEY, M.D.
PHILADELPHIA.

The somber results of the knife and curette in the treatment of cancer of the cervix uteri are nowhere shown more distinctly than in that beautiful and monumental work of Cullen,[1] in which science has been enriched by the careful study of 141 cases operated on by master hands; seventy-three by hysterectomy and sixty-eight by curettement. Of the total number but fifteen, or about 10 per cent., were still living when the book went to press. An even more gloomy result was reported in a discussion in this Section at the Saratoga Session,[2] where one operator was quoted as saying that he had operated on 482 cases of cancer of the cervix, of which but two were living.

From experimental studies of the autoinfectivity of cancer, notably summarized in a chapter of the work mentioned, it is evident that this small percentage of cures in operable cases may be due in part to a reimplantation of the growth in the cut edges. This has been partially provided against by the Byrne method of cauterization by the galvanocaustic knife, and more recently by the electric cooking process of Skeene, revived by Downs. While the latter process is somewhat clumsy, and difficult of application through the vagina, owing to the large instruments and great heat required, it is evident that both methods are distinct advances in the treatment of cancer of the cervix by a probable elimination of operative infection.

A far more thorough sterilization is, however, possible by the use of the electrochemical method advocated by the writer for some years, for by this method no preliminary opening of the lymph and blood channels, with possible instantaneous admission of cancer cells, is required, the growth being destroyed and sterilized *in situ,* and the sterilization then carried to any desired depth and in any desired direction by small, easily-handled instruments, with complete protection of the external parts from accidentally straying force, and without appreciable heat production.

A powerful electric current is employed in this method for the development, within the substance of the growth, of nascent oxychlorids of mercury and zinc, from a union of electrolytically freed oxygen and chlorin with the mercury and zinc of an amalgamated electrode. These nascent salts thus produced during application are radiated in all directions by the continued flow of the current, devitalizing the protoplasm of the neighboring cells, particularly the better conducting lowly vitalized malignant cells, and the outflow may be governed and directed by the operator until both the center and the periphery of the growth are devitalized and sterilized, the destroyed tissues assuming a whitish-gray aspect.

The time required for the total destruction of an average cancer of the cervix varies from a half hour to two hours, with a current of 500 to 600 milliamperes, the patient being under a general anesthetic, as for a major operation. In certain early stages of malignant disease of the cervix the same results may be accom-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

1. Cancer of the Uterus, T. S. Cullen, D. Appleton & Co., New York, 1900.

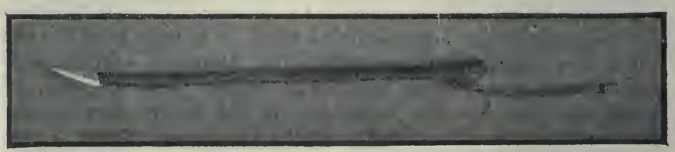
2. The Journal A. M. A., July 26, 1902.

plished by several prolonged applications of 150 to 200 milliamperes, which may be borne without an anesthetic.

The immediate results of a thorough devitalization and sterilization of such a growth are the arrest of pain, hemorrhage and odor; and the slough produced is separated by the process of Nature in from ten days to three weeks. The bloodless destruction of the apparent portions of the growth do not, however, exhaust the full value of this application, for beyond the limit of absolutely destructive action there will be produced by a prolonged application a radiating zone of partial impregnation with the mercuric salt of sufficient strength to devitalize malignant cells, while the normal tissue elements are only irritated. It is this zone of sterilization that makes the value of this method absolutely unique, though the readiness with which the immediate area of necrosis is produced and directed at will is alone sufficient to attract the attention of the surgeon.

DETAILS OF THE OPERATION.

It is probable that the current required in a major application of mercuric cataphoresis in a case of cancer of the cervix may be obtained from the 110-volt Edison mains, but I have preferred to use a somewhat greater voltage, about 160 volts, obtained from specially built carbon-zinc-acid batteries of a total of about eighty cells. Two thirty-cell and one twenty-cell battery are connected in series to obtain this number. The batteries must be in the best order, freshly amalgamated, and with fresh fluid. The only other pieces of apparatus required are a good meter and controller adapted for the control and measurement of the large current used.



The negative dispersing pad on which the patient lies is placed on the operating table, which is preferably of wood to prevent straying of the current, covered with some material to make it slightly yielding to the shape of the patient's back. This pad is composed, from below upward, of a rubber sheet, on which is placed a lead plate as large as the patient's back, connected with the negative pole of the battery, and over the lead plate a very thick absorbent pad composed of nine or ten layers of heavy cotton material thoroughly saturated with warm water. Care must be taken that the lead plate is entirely covered so that the patient, who lies on it, does not come in contact with the metal.

On the pad the patient is placed in the dorsal position with the legs supported by a leg holder. After the patient is in position a deflated Kelly pad is slipped beneath the buttocks to prevent too short a circuit for the return current in this situation, and to provide drainage for the waste water used in keeping the vagina cool.

On a table at the side of the operator is placed a tray containing several appropriately shaped zinc electrodes with their tips coated with mercury, a glass cup containing dilute sulphuric acid to facilitate the renewal of the mercury on the electrodes, and another with several ounces of liquid mercury. The progress of the work is best observed by a miniature lamp and a Fergusson speculum when the electrode is removed from time to time, and these articles should, therefore, be at hand.

The best result in the cataphoric destruction and sterilization of cervical cancer is obtained from the mixed electrolytic salts of zinc and mercury, rather than from the pure mercuric salts from gold-mercury electrodes. This is partly due to the difficulty in controlling a liquid electrode surface in this situation. The accompanying illustration shows the shape of the zinc-mercury instrument that I have found to be most convenient for the purpose. You will observe that it is heavily coated with non-conducting materials fused on it except at the active surface.

The apparatus having been connected up and tested, the patient is etherized and placed on the table, with careful adjustment of the pad, and the operation begun by inserting the point of the electrode into the growth and turning the current on gradually until the desired strength has been attained. The operator's finger should be kept near the seat of action, and when an uncomfortable rise of heat is observed the rubber tip of a fountain syringe should be inserted within the vagina alongside the finger and a little cold water allowed to flow. This effectually keeps down the heat otherwise developed when so great a current is concentrated at such a small point as a single electrode. At the end of fifteen or twenty minutes the current should be turned off, the site of action examined, and a freshly amalgamated electrode placed in such new position as desired. At the end of a time varying from a half hour to two hours the whole of the growth will be destroyed and a moderate region beyond sterilized. The completeness of the destructive action is apparent on visual examination, but much more thoroughly attested by the changed conditions indicated to the examining finger, for it is characteristic of a cancerous growth under this process to become progressively soft during the flow of the chemical, and the test of a complete

softening of the indurated areas is the signal for the termination of the operation.

The after-treatment of the patient is merely expectant, but little pain being felt and this only during the first twelve hours.

The writer does not present this method to the profession as a cure-all by any means, but he does believe that it is the most effectual method for the treatment of the early stages of all varieties of malignancy in this situation, unless the recent attempts to apply radiotherapy within cavities can be improved; and it is evident that when applied in inoperable cases it will not only give a fighting chance of ultimate cure, but, by reason of the immediate relief it affords to the hemorrhage, pain and odor, it will become a valuable palliative and prolong life when a cure is impossible.

DISCUSSION.

DR. A. M. HAYDEN, Evansville, Ind.—I wish to know what results Dr. Massey has had; whether he has any statistics and any apparent cures, how long they have lasted, what stage they were in and whether they were diagnosed before the appearance of the offensive odor from the uterus.

DR. H. E. PEARSE, Kansas City, Mo.—I wonder why, in place of investigating this matter during the past years, the profession has always given it the very coldest welcome and the warmest opposition. In reality, it is a perfectly logical procedure. I tried it in three cases, and all three were failures, but I have not abandoned hope, because for fifteen years it was my pleasure to see case after case go to the surgeon for relief by operation, and it was my dismay to see every one of these cases come back to me, as a general practitioner, and seek for the relief that surgery could not give them. During five years I have seen an unlimited line of failures in

the operation for radical cure of uterine cancer. I now have one perfectly healthy case after nine years of postoperative life. We should look on this work of Dr. Massey's with at least a little bit of expectancy, and I hope he will tell us what he has accomplished.

Dr. G. B. Massey—The cataphoric method for the destruction of cancer has been used by me in as many as 63 cases in all portions of the body, but I have only had the opportunity to employ it in 7 cases of cancer of the cervix, and only 4 of these were treated exactly as described in the paper. There has been but one absolute and final success of the 7 treated—a case that had not been operated on previously, and in this case the patient remains well after the lapse of six years. All the rest were recurrences after knife operations, and, with the exception of one case that proved fatal from peritonitis within six days, they were all greatly benefited for a time, usually dying ultimately from a metastasis that must have been implanted before the application. But, whether the patient is suffering from metastasis or not, it is my conviction that this method offers the best chance for either the relief or cure of cancer in this situation.

EMPYEMA OF THE FRONTAL SINUS.

[Through inadvertence, the discussion at the New Orleans session on the paper of Dr. C. A. Thigpen, Montgomery, Ala., was omitted from The Journal, Nov. 14, 1903, page 1209. It was as follows:]

DISCUSSION.

Dr. Robert C. Myles, New York—The classic operation Dr. Thigpen performed is, in my opinion, always the proper one in this class of cases. He first provided for permanent drainage by removing the anterior end of the middle turbinal, some of the ethmoid cells, and also probably a part of the nasal process of the maxillary bone.

Dr. Gordon King, New Orleans—I want to emphasize the necessity in these chronic cases of a radical method of operation. I think all of us have had very disagreeable experiences very often of having these cases dragging on indefinitely by any method we may pursue. When the mucous lining of the cavity has become degenerated, sometimes forming polypoid masses that may almost occlude the cavity, it is necessary to scrape out the cavity. In those cases I do not see any other course of treatment to pursue except the radical method of opening the sinuses widely and then obliterating the cavity, whether you leave the cavity to become obliterated by a slow process of granulation, or close it up immediately and allow it to fill up from the inside, with the establishment of intranasal drainage. Even that is sometimes unsatisfactory, but not so unsatisfactory as the open method where you pack it as an external wound. Those cases are extremely unsatisfactory in their course. In the first place, it takes eight or nine months for them to finally heal up, and you have not only a depression but also an unsightly scar in a prominent place. A method with which I have had considerable experience has in a measure overcome that defect. It is the Ogston-Luc method, by which you open the cavity, clean it out and close it up, and the wound will heal beautifully, even after a large opening. It will go on very nicely for ten days or two weeks, however, and then it may again become obstructed. That takes place before the postoperative obliteration of the cavity. You are then forced sometimes to reopen the cavity and treat it externally. On this account some observers have lost confidence in that method. To overcome the difficulties an operation has been perfected which I think is satisfactory. There is a deformity of the face left, but with paraffin injections I think that can be overcome. The cavity is obliterated by the transplantation of a periosteal-cutaneous flap into the wound. The cavity is opened widely; it is scraped out thoroughly, no attention is paid to the intranasal drainage, and the wound is sutured afterward, except the external part of the wound. Obliteration of the cavity takes place immediately and recurrence is almost impossible. The usual course of these cases is an uneventful recovery in two or three weeks. I favor a modification of that method, which solves the question of drainage. That is simply complete obliteration of the cavity and intranasal drainage combined, so that the entire wound can be sutured up and drainage can be secured through the nose. There is no danger of the formation of a fistula. I have adopted that recently in a double empyema where the cavities were enormous and opened into one chamber. The process had gone on to the destruction of sight on one side before I saw the case. Healing took place in ten days with no bad features whatever following. That I believe to be one of the best operations we have in these cases.

Dr. Otto T. Freer, Chicago—In Killian's recently perfected operation for the complete obliteration of the frontal sinus in cases of chronic suppuration, he removes the entire front wall of the frontal sinus with the exception of a slender bridge of bone whose lower border is the supra-orbital margin. In addition he resects the frontal, also called nasal, process of the superior maxillary bone, making a broad opening as far back as the lachrymal bone, as far toward the center as the nasal bone and as far upward as the lower margin of the bridge mentioned. This gives most convenient access to the outlet of the sinus, the frontal and anterior ethmoidal cells and middle turbinated body. Killian also removes the orbital floor of the sinus so that the orbital fat may rise to help fill the hollow left by the obliterated sinus and the deformity thus becomes less than if only the front wall were removed. Killian's results have been perfect and his photographs show very slight disfigurement. I have done the operation on the cadaver only, but have been impressed with the ease of its performance, its precision and the easy access obtained to the ethmoidal cells both anterior and posterior. It is also possible to reach the sphenoidal sinus through the opening left by the removal of the frontal process.

Dr. Adolph O. Pfingst, Louisville—I wish to commend the method of Kunst and Luc, mentioned by a preceding speaker. I believe the operation described by Kunst should be done to get the best drainage. At first it struck me that drainage would not be proper in these cases. It has been suggested to introduce drainage tubes, but in the limited number of cases which I have treated I did the operation without drainage tubes. In two cases operated on by this method there has been no recurrence. There has been considerable work done on this subject in late years, but we have not really done enough along this line. Most of us do not care to see these cases come to us because at the best they are ungrateful in their results. We ought to give the subject more attention.

Dr. George L. Richards, Fall River—The question of deformity must not be too lightly overlooked. Deformity in the United States and deformity in Germany are two very different things. I have seen cases in Jansen's clinic with eyes looking in different directions; if such cases were to occur in this country they would be an unpleasant advertisement. Sometimes it may be just as well to be a little less radical and take a little longer to do the radical operations recommended by some of the German operators. You can put in a drainage tube and all that, but the opening into the nose usually sooner or later closes. You can maintain the external opening for a long time by putting a small silver or gold tube in the wound. I have had dentists make them with a little rim so they can not slip in. Cases sometimes show bulging from pus after apparent cure and the wound can be reopened if necessary rather than to do at first the very radical operation. The tube can be kept in almost indefinitely when the operation is done above the inner angle of the eye, and finally it may be removed and the hair of the brow grows over the wound so that the scar is almost imperceptible.

Dr. H. Dupuy, New Orleans—Dr. Lake of England has recently recorded three fatalities in his own practice where he had completely closed the wound, although he had free irrigation through the nose. It seems that the diploë of the frontal bone is very likely to receive infection, and by this means in two of his cases infection was carried to the brain. A recent experience in a case I have just reported to our state society has inclined me to the method of incomplete closure of the wound. Presuming there has been made a horizontal incision to the eyebrow, then after the operation I put in two or

three sutures from the outside, leaving an opening along the median line through which the packings may be introduced and drainage secured. In less than six weeks, in the case of a small frontal sinus, it was completely closed by granulations.

DR. E. FLETCHER INGALS, Chicago—I reported a case not long ago in which I succeeded in curing suppuration of the frontal sinus by a 4 per cent. solution of protargol, after the suppuration had continued for ten years. The man had been under my care for some time, but he had refused operation. By antiseptics we can frequently cure these cases without operation. In the cases in which I have made a radical operation I have put in a drainage tube from above; this tube has a flange at the upper end to prevent it from slipping down, and is somewhat funnel-shaped at its lower half so it will not work up. In one case where the posterior wall of the frontal was found completely destroyed at the time of operation I kept the external wound open between the eyebrows by a short rubber drainage tube flanged at both ends. This enabled the patient to cleanse the cavity easily. She refused to have the wound closed, although there was free drainage through the nose. The last I saw of her, about two years after the operation, the wound was still open. It is well to leave the external opening in such cases until we are sure suppuration has ceased.

DR. C. A. THIGPEN, Montgomery, Ala.—It was not my intention to dwell on the various operative procedures for frontal sinus disease. With regard to the operative technic the more I have operated the more conservative I have become, and before doing any external operation, the anterior portion of the middle turbinate should be removed and the probe introduced into the sinus to ascertain its upper boundary; from this point I open the cavity and drill downward and backward into the nose. Special attention should be directed to the nasal process of the superior maxillary bone, drilling away as much of it as possible, as advocated by Dr. Myles. Since following this teaching I have not failed to relieve my cases, and thus forego the necessity of a more mutilating operation.

THE CULTIVATION OF TRYPANOSOMA BRUCEI.

A PRELIMINARY NOTE.

(From the Hygienic Laboratory, University of Michigan.)

FREDERICK G. NOVY, Sc.D., M.D.
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF MICHIGAN,
AND
WARD J. McNEAL, A.B.
FELLOW OF THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.
ANN ARBOR, MICH.

At the New Orleans meeting of the American Medical Association we presented before the Section on Pathology and Physiology the results of our work on the cultivation of the ordinary rat trypanosome, *Trypanosoma lewisi.* The paper itself has appeared since then in the Vaughan *Festschrift.*[1] The results obtained mark a distinct advance in our knowledge of the animal parasites since this was the first time that a pathogenic protozoön was successfully cultivated and its relation to the disease demonstrated by inoculation of pure cultures. At that time we expressed the belief that the methods employed would probably be found to be applicable to other trypanosomes, and this view we have been able to confirm with reference to one of the most important organisms of this group, namely, *Trypanosoma brucei,* the cause of nagana or the tsetse-fly disease of South Africa.

The nagana material necessary for this work was kindly supplied us by Dr. H. Wolferstan Thomas, late fellow at McGill Medical College and now of the Liverpool School of Tropical Medicine. We take this occasion to express our grateful appreciation of the courtesy thus extended. It should be further stated that this material is lineally descended from that brought to England from Zululand in the fall of 1896 by Dr. Waghorn, and therefore it is the same as that employed by Kanthack, Durham and Blandford, by Plimmer and Bradford, by Laveran and Mesnil and other European workers, with the exception of Martini.

It has been shown that the *Trypanosoma brucei* dies out very rapidly in the cadaver, sometimes within a few hours, and that this occurs even when the blood is transferred to a tube. The longest that any one has been able to keep the parasite alive *in vitro* has been about six days. Under these conditions no evidence of multiplication has been observed. The virulence of the blood when kept in tubes is preserved longer than when the blood remains in the cadaver, but, only exceptionally, has it been found to persist up to the fourth day. It seemed as if this organism was essentially an obligative parasite and as such incapable of existing outside of the living animal.

The methods which we have employed are the same as those used for cultivating the rat trypanosome and for that reason need no description at this time.

The culture medium employed in all of our work was ordinary nutrient agar, containing variable amounts of defibrinated rabbit blood. In the water of condensation, which accumulates in tubes or flasks containing this medium, the rat trypanosome grows readily and luxuriantly. No difficulty is experienced in starting an initial culture of this trypanosome from the blood of an infected animal.

The nagana trypanosome does not take readily to this same medium, and a great deal of difficulty was experienced in obtaining cultures of this organism. When, however, an initial culture is once obtained, and the parasite has become used to its new soil, the subsequent cultivation is more easy.

Notwithstanding numerous modifications of our technic, all attempts to obtain cultures from the first twenty-five nagana animals failed. In the inoculated tubes the trypanosomes would usually die out on about the 5th to the 7th day; exceptionally they were found to be still alive on the 9th, 10th, 11th, 14th, and even on the 18th day. In these cases only a few survivals were left, most of the parasites having undergone degeneration and died. When the culture tubes were placed in the incubator the trypanosomes died out in two or three days.

The virulence of the fluid in the culture tubes was found to disappear usually on about the 4th or 5th day. In two instances, however, the surviving trypanosomes were found to be infectious on the 9th and on the 10th day. The infection in these instances was clearly due to the few cells which survived, since no evidence of multiplication could be detected. Frequently, such material, though containing living trypanosomes, failed to infect animals; a fact which goes to show that attenuation of the nagana parasite is possible. This we have been able to definitely establish with the pure cultures subsequently obtained.

From the second series of twenty-five nagana animals—white mice, rats and guinea-pigs—we succeeded in obtaining four positive cultures from as many different animals. The first of these, Culture A, was started August 27, and since that time has been carried through six successive generations *in vitro.* At the present time, November 12, it is in its seventh generation. In other words, this culture has been maintained under artificial

1. Contribution to Medical Research dedicated to Victor Clarence Vaughan, Ann Arbor, Mich., 1903, George Wahr, p. 549.

conditions for 77 days, and there is no apparent reason why it should not be cultivated indefinitely.

Culture B was started September 7, and during the next 52 days was carried through two generations. The third generation has as yet shown no growth, but probably will.

Culture C was started September 10, and is at the present time (63 days) in its third generation and is doing well.

Culture D was inoculated September 12, and the original tube contained living trypanosomes as late as the 45th day. A second generation, however, failed to take, probably owing to the feeble condition of the parasite.

It is difficult to furnish any satisfactory reason why only four animals out of fifty examined should have given positive results. There are obviously injurious substances present in the blood which tend to prevent the growth of the trypanosomes and eventually cause their destruction. Our efforts at present are directed at ascertaining the nature of these poisonous substances and to find means whereby this action may be counteracted.

When the nagana blood is planted on blood agar most of the trypanosomes rapidly die out; so much so, that an examination may fail to show a single living form and thus give rise to the impression that the culture is a failure and lead to the discarding of the tubes. And yet, a few surviving organisms are present and succeed in adapting themselves to the changed condition, and from these the culture begins. The whole phenomenon is very suggestive of a survival of the fittest.

The cultures of *Trypanosoma brucei* may be developed at room temperature, or at 25 C., or even at 34 C. At room temperature the growth is slow to come on, and, for that reason, the cultures will remain alive the longest. We have repeatedly found such cultures alive as late as the 45th day. When developed at 25 C., an excellent growth may be obtained in from 7 to 10 days, and may persist for several weeks. On the other hand, at 34 C. growth is possible, but the cultures die out in about a week. It may be stated at this point that when fully developed and actively motile cultures are placed at 34 C. they rapidly lose their virulence and die out in a few days.

The rat trypanosome, as already stated, grows readily on the blood agar medium and can be isolated from animals in nearly every trial. In this respect it will be seen that it differs materially from the nagana trypanosome, which only exceptionally yields to culture. While the former grows readily on media containing blood and agar in the proportion of 1 to 2, 1 to 5, and even 1 to 10, the latter can not be cultivated on a medium containing less than 1 to 1 of blood.

This fact may be utilized to separate the two trypanosomes when present in mixed infection in a rat. When a rat which contains *Tr. lewisi* is infected with *Tr. brucei*, both parasites appear in the blood and can be recognized, as Koch pointed out 5 years ago, by examining the blood. By injecting blood showing mixed infection into a dog, Koch was able to separate the nagana parasite from that of the rat. By means of our cultivation method, it is possible to plate out, as it were, the two organisms and obtain these in pure culture. The blood of the rat showing mixed infection when planted on blood agar (1 to 2), will give a rich growth of only the rat trypanosome, since the nagana parasite is unable to grow on this medium. If at the same time a portion of the blood is inoculated into a mouse or animal other than a rat, the nagana trypanosome will develop and eventually cause death. From the blood of this animal, by inoculating a 2 to 1 blood agar medium, it may be possible to obtain a pure culture of *Tr. brucei*.

The *Tr. brucei* as found in the blood of an animal is exceedingly virulent and an extremely minute amount of such blood is sufficient to cause the death of an infected animal. The result is much the same whether the parasites are very numerous or so few as to be scarcely detected under the microscope. From this it would appear that the virulence of *Tr. brucei* is a fixed and constant quantity.

TABLE SHOWING RESULTS OF INOCULATION OF CULTURES DEVELOPED AT 25 C.

	Culture and Generation.	Blood-agar.	Age of Culture.	Date of Inoculation.	Date of Appearance of Trypanosomes.	Date of Death.	Time Before Death.
Mouse 3.	A iii. . .	2:1	7 days	Oct. 5	Oct 14.	Oct. 16 . . .	11 days.

The intraperitoneal injection of virulent cultures of *Tr. brucei* causes death in mice and rats in about 7 or 8 days, exceptionally as late as 11 days. When it is remembered that these animals usually die in from 3 to 5 days after the inoculation of virulent blood, it will be seen that these cultures are already somewhat attenuated. The retarded death is not due, as might be supposed, to the injection of a small number of trypanosomes, since the cultures injected are extremely rich in actively motile parasites. In a few instances, our mice and even rats died in 3½ and in 5 days.

A study of the artificial cultures, however, shows that the virulence of this organism is variable and that it can be altered at will. This is an exceedingly important fact, since by means of attenuated cultures it may be feasible to secure the much-desired immunization.

The following table shows the results obtained by inoculating cultures developed at 25 C. These results prove that the organism cultivated is in reality the nagana trypanosome. Moreover, since these inoculations are made with pure cultures they furnish the final evidence, if it be needed, that this trypanosome is the cause

of nagana. The trypanosomes which appear in the blood of the infected animals are in every respect the same as those met with in the animals infected with nagana blood.

When a virulent culture, developed at room temperature or at 25 C., is placed at 34 C., for a day or two it becomes less active and non-infectious. The loss of virulence is not due to the death of the trypanosomes, for these may remain alive and apparently uninjured for several days. Eventually, however, they develop numerous globules within the cells, change into spherical involution forms and finally die out.

Our experiments on immunizing animals against nagana are not far enough advanced to warrant making any definite statement. An inspection of the table will show that in one experiment two control mice, Nos. 9 and 10, died in 7 and 7½ days, while three animals which received a single injection of living, but non-virulent trypanosomes, died in 8½, 9 and 9½ days after infection. This would indicate that a slight protection had been afforded by the single injection. Of course, more definite experiments will be needed before positive conclusions can be drawn. Such work is at present being carried on.

The cultivated *Tr. brucei* is readily distinguishable from that of *Tr. lewisi*. Thus, while the latter has almost homogeneous contents, the former is characterized by the presence of two or more bright, highly refracting globules, usually placed near the anterior or flagellar end. At times, the number of these globules is increased, as when the culture is kept at 34 C. In size these globules may attain one micron.

The *Tr. lewisi* varies considerably in size. Some forms are found which are not more than one or two microns long, not including the whip. Others are about the diameter of a red blood cell, while usually they average about 15 to 20 microns.

The *Tr. brucei* shows less variation in size and averages 15 microns in the living condition.

The motion of the two organisms is entirely different. Thus, while the rat trypanosome is frequently seen darting about in an almost straight line and with great speed, the nagana parasite usually shows only a slow, wriggling motion and scarcely departs from its place. The wave motion passes slowly along the thick undulating membrane and imparts the appearance of spiral rotation to the entire cell.

The most striking difference is perhaps seen in the appearance of the colonies or aggregates. The *Tr. lewisi* forms aggregates of spindle-shaped forms, consisting at times of many hundreds and even of thousands of cells. The cells composing these masses show a slight swaying motion and their whips seem to be directed centrally. The *Tr. brucei* rarely forms masses of more than 10 or 20 cells. The individuals are long, narrow and show the peculiar writhing motion. The flagella are directed outward and the appearance of the whole may be compared to the snakes on a Medusa head. The stellate group with the bright, refracting globules within the cells, suggests a jeweler's "sun-burst."

This paper is intended to briefly summarize the main facts arrived at in our studies up to the present time. The full details may be expected in a later publication.

Physicians, as a rule, do not write enough about their experiences. They have valuable practical knowledge which it would benefit themselves and the profession to publish. But they wait, because they think it necessary to write a long, big-worded article when really a short letter or description would be of more interest.—*Medical Summary.*

AN ANALYSIS OF FIFTEEN HUNDRED CASES OF TUBERCULOSIS

DISCHARGED FROM THE ADIRONDACK COTTAGE SANITARIUM FROM TWO TO EIGHTEEN YEARS AGO.

LAWRASON BROWN, M.D.
Resident Physician, Adirondack Cottage Sanitarium.
SARANAC LAKE, N. Y.

In a disease of so relapsing a nature as tuberculosis the inexorable test of time is rarely applied in the study of the results obtained by any form of treatment. The object of this research has been to apply this crucial test to the permanency of the beneficial effects which are undoubtedly obtained by the sanatorium treatment of pulmonary tuberculosis. The results of treatment in this disease vary directly with so many factors that it is exceedingly difficult to compare the results obtained by different observers. The use of different classifications, and in some instances the different interpretation of the same classification render any comparison a difficult task. Take, for example, the terms "apparently cured" and "cured." One observer applies them to patients who have gone a few months without symptoms and whose physical signs, if at all abnormal, are indicative of a healed lesion. Another thinks the time should be six months, a third one year, and possibly interprets the physical signs differently. It is to be hoped before long we shall have in America one classification adopted by the various sanatoriums. The classification adopted by Dr Trudeau has been retained in these statistics, not because he claims it to be entirely satisfactory, but because it is the one which has been applied from the first and throughout the past eighteen years to the cases on which this study is based. The classification is as follows:

Incipient Stage.—Slight local, with little or no constitutional involvement.

Advanced Stage.—The localized disease process extensive or in an advanced stage, or slight local pulmonic invasion with rather marked constitutional involvement or with complications.

Far Advanced Stage.—Marked signs of pulmonic disintegration with marked constitutional symptoms.

Improved Condition.—Physical signs showing process less active, or general health improved with symptoms relieved or abated.

Arrested.—No activity in process in lungs, with absence of fever and other constitutional symptoms.

Apparently Cured.—Abnormal physical signs absent, or if present only slight and indicative of healed lesion. Absence for some months of pyrexia and of sputum or of sputum containing tubercle bacilli.

Perfectly Cured.—Abnormal physical signs absent, or if present only slight and indicative of healed lesion. Absence for two or more years of pyrexia and of sputum or of sputum containing tubercle bacilli.

In order that the results of the treatment by the fresh air and rest cure at the Adirondack Cottage Sanitarium may be fully understood, it is necessary to consider for a moment the difficulties under which the work was begun. When the institution was first started, Dr. Trudeau, owing to popular prejudice, had great difficulty in persuading patients to enter, and as a result many cases entirely unsuited for sanatorium treatment were admitted. A glance at the relative proportion of incipient, advanced and far advanced cases admitted during the first few years will make this clear. Of the first 500 patients 21 per cent. were

in an incipient stage, 48 per cent. in an advanced, and 29 per cent. in a far advanced stage. During the year ending Nov. 1, 1902, 165 patients were discharged. Of these on admission 31 per cent. were in an incipient stage, 46 per cent. in an advanced and 3 per cent. in a far advanced stage. Had such figures obtained during

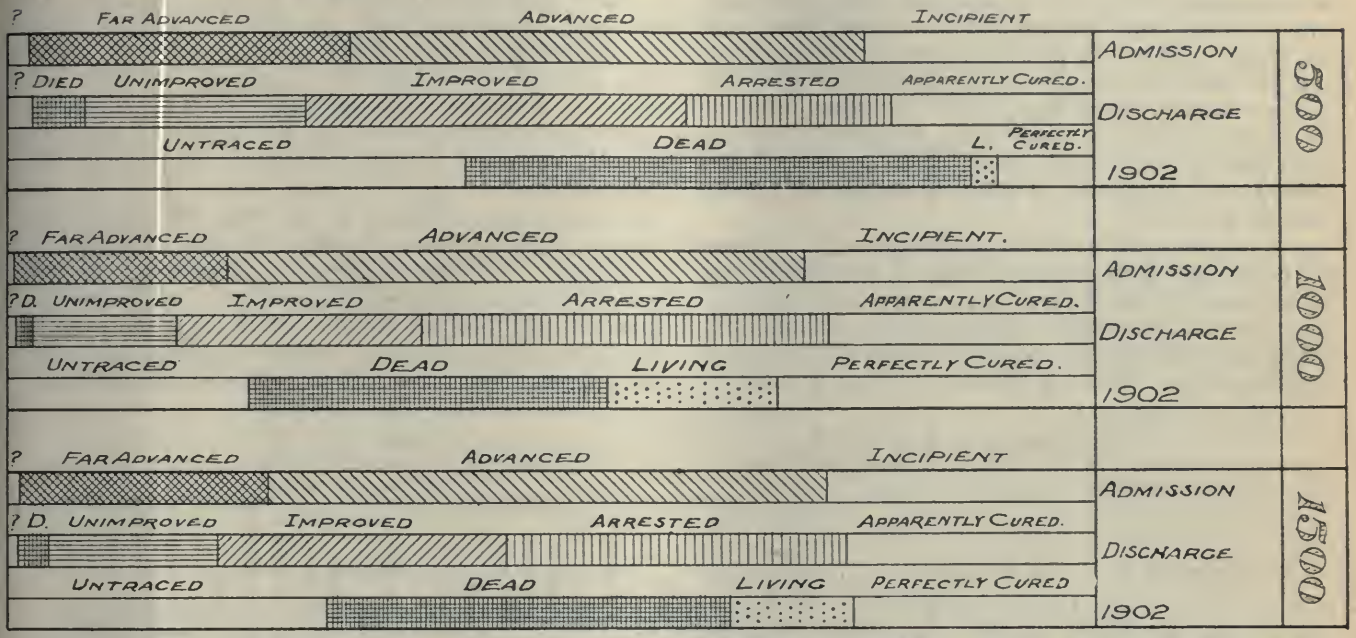

Chart 1.—Graphic representation of Tables 1, 2 and 3. The space marked ? indicates doubtful cases. The space marked "living" includes chronic and relapsed.

the first years of the institution the results would no doubt be very different.

I.—RESULTS OBTAINED IN 500 CASES DISCHARGED FROM EIGHT TO EIGHTEEN YEARS AGO.

The first 500 cases were admitted during a period extending from May 12, 1885, to July 1, 1893, a little more than eight years. The last of the patients was discharged nine years ago. Owing to the fact that it has not been possible until recently to trace the patients systematically many of the early cases have remained untraced. These untraced cases compose 43 per cent. of the first 500.

A.—*Incipient Cases.*—It has been long recognized that the curability of pulmonary tuberculosis depends directly on the stage of the disease. This has been found to hold true among these cases. The 103 incipient cases were discharged as follows: Apparently cured, 73 (71 per cent.); arrested, 12; improved, 12; unimproved, 6. At the present time there are: Well, 23 (22 per cent.); arrested, 1; relapsed, 2; dead, 26; untraced, 51. Of the 73 apparently cured cases 18 are well, while 3 of the 12 arrested, 2 of the 12 improved and none of the 6 unimproved are well. It is interesting to note among the incipient cases that at the present time about the same percentage of cures are obtained from those discharged apparently cured, arrested and improved. Twelve of the 73 cases discharged apparently cured, 2 of the arrested,

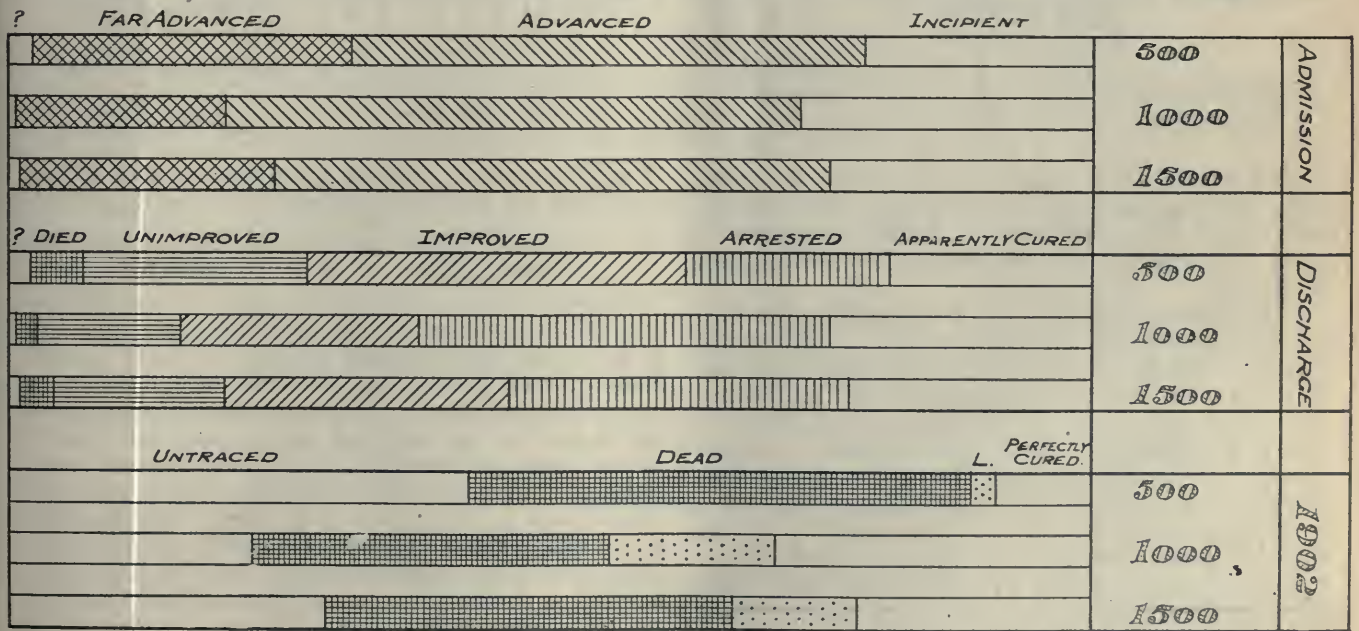

Chart 2.—Graphic comparison of condition on admission, on discharge, and in 1902.

8 of the improved and 4 of the unimproved are dead. The untraced cases are distributed according to the condition on discharge as follows: Apparently cured, 40; arrested, 7; improved, 2; unimproved, 2.

If, however, for a moment we exclude those cases that have not been traced, we find that 44 per cent. of the incipient cases that have been traced are well, 2 per cent. arrested, 4 per cent. relapsed and 50 per cent. dead. Of the traced incipient cases discharged apparently cured, 54.5 per cent. are well, of those arrested 60 per cent. (out of 5 cases), of the improved 20 per cent. Many of the untraced cases are undoubtedly dead, and while the percentage of cured cases would in all probability not reach 44 per cent., still it would be considerably more than 22 per cent.

B.—*Advanced Cases.*—Forty-eight per cent. of these 500 cases were in an advanced stage of the disease. Of the 165 cases discharged during the last year 64 per cent. were advanced, showing in the number of advanced cases admitted a much greater increase than in the number of incipient cases. Without question a large number of patients do not come under the observation of a physician until they are in an advanced stage. The 240 advanced cases were discharged as follows: Apparently cured, 20; arrested, 62; improved, 124; unimproved, 28; died, 6.

At the present time 17 (7 per cent.) of these are well, 5 arrested, 1 chronic, 117 (48 per cent.) dead and 100 untraced. Of the 20 apparently cured cases there are 11 well, while 4 of the 62 arrested, 2 of the 124 improved and none of the 28 unimproved cases are well. Two of the apparently cured cases are dead, 33 of the arrested, 55 of the improved, 21 of the unimproved. The untraced cases were as follows: Apparently cured, 7; arrested, 21; improved, 65; unimproved, 7. If the untraced cases are omitted the following figures are obtained: Well, 14 per cent.; arrested, 3 per cent.; dead, 84 per cent. Of the 13 apparently cured cases that have been traced 11, or 84 per cent., are well.

C.—*Far Advanced Cases.*—It is most gratifying to note the decrease in the far advanced cases. Of the first 500 cases 29 per cent. were far advanced, while last year the percentage was only 3. The 146 far advanced cases were discharged as follows: Apparently cured, 0; arrested, 19; improved, 41; unimproved, 70; dead, 16. At the present time there are: Well, 2; arrested, 1; chronic, 1; dead, 90 (62 per cent.); untraced, 52. The 2 cases now well were discharged as unimproved. Of the 19 arrested cases 12 are dead, while 22 of the 41 improved, 40 of the 70 unimproved cases are dead. The untraced cases are distributed as follows: Arrested, 6; improved, 18; unimproved, 28. If the untraced cases are omitted it is found that 2 per cent. are well, 1 per cent. arrested, 1 per cent. chronic and 96 per cent. are dead. To find after a lapse of nine years 4 far advanced cases alive is worthy of note, and the fact that 2 have apparently recovered is most interesting (and recalls the *spes phthisica*.

D.—*Summary of Results in the First 500 Cases.*—To sum up, the condition of the first 500 cases at present is as follows: Well, 42 (8 per cent.); arrested, 7 (1 per cent.); relapsed, 2; chronic, 2; dead, 233 (46 per cent.); untraced, 214 (44 per cent.). In 11 cases the records were incomplete, and as the patients could not be traced they have not been taken into account except in the total.

	Died at sanitarium	16	11	0	0	0	0	0	0	0	0	16	100	0	0
	Total	146	..	2	2	1	1	0	0	1	1	90	61	52	35
Incomplete records		11	..	0	0	0	0	0	0	0	0	0	0	11	100
Grand total		500	..	42	8	7	1	2	1	2	1	233	46	214	43

At the present time there are: Well, 2; arrested, 1; chronic, 1; dead, 90 (62 per cent.); untraced, 52. The 2 cases now well were discharged as unimproved. Of the 19 arrested cases 12 are dead, while 22 of the 41 improved, 40 of the 70 unimproved cases are dead. The untraced cases are distributed as follows: Arrested, 6; improved, 18; unimproved, 28. If the untraced cases are omitted it is found that 2 per cent. are well, 1 per cent. arrested, 1 per cent. chronic and 96 per cent. are dead. If only the traced cases are considered we find 15 per cent. well, 2.4 per cent. arrested and 81 per cent. dead.

II.—RESULTS OBTAINED IN ONE THOUSAND CASES DISCHARGED FROM TWO TO EIGHT YEARS AGO.

In order to compare the results obtained more recently with the earlier results 1,000 cases discharged from two to eight years ago have been studied. Of these patients 26.3 per cent. were in an incipient stage, showing in comparison with the first 500 cases a decided decrease in the number of far advanced cases, a material increase in the number of advanced and a decided increase in the number of incipient cases. The actual number of incipient cases increased over 31 per cent. On comparing the results of these cases with the earlier group it must not be overlooked that the earlier cases have all been discharged from eight to eighteen years, while none of the later group have been discharged more than eight, and some only two years.

A.—*Incipient Cases.*—The 263 incipient cases were discharged as follows: Apparently cured,[1] 172; ar-

1. Cases that remained at the sanitarium less than one week have been omitted, except in the tables.

rested, 71; improved, 17; unimproved, 2. At the present time there are: Well, 147 (57 per cent.); arrested, 12; relapsed, 12; chronic, 7; dead, 28 (11 per cent.); untraced, 57. Of the 172 apparently cured cases 113 (66 per cent.) are well, while 27 (38 per cent.) of the 71 arrested, 7 of the 17 improved and none of the unimproved are well. Ten of the apparently cured cases, 14 of the arrested, 2 of the improved and 2 of the unimproved cases are dead. The untraced cases are as follows: Apparently cured, 35; arrested, 16; improved, 6.

B.—*Advanced Cases.*—The 538 advanced cases were discharged as follows: Apparently cured, 70; arrested, 276; improved, 137; unimproved, 50; dead, 4. At the present time: Well, 134 (25 per cent.); arrested, 46; relapsed, 27; chronic, 38; dead, 178 (33 per cent.); untraced, 115. Of the 70 apparently cured cases 43

SUMMARY OF RESULTS IN 1,000 CASES.

In other words, the condition at present of these 1,000 cases is as follows: Well, 28.7 per cent.; arrested, 6 per cent.; dead, 33.6 per cent.; untraced, 22 per cent. From this it is seen that 444 patients are alive, 336 dead and 220 untraced. Bearing in mind the fact that the patients of the first group were all discharged before the earliest cases of the second, it nevertheless appears that the patients of the second group have done better since discharge than those of the first group. Many of the untraced cases in both groups are undoubtedly dead. The reason why the percentages of the cases that have died do not vary more is probably due to the fact that in the second group a much larger percentage of the cases that have died have been traced. For this reason it is well to compare only the cases still alive in each group. Of the first group 10 per cent. of the cases are alive and 8 per cent. are well from eight to eighteen years after discharge. Of the second group, 44 per cent. of the cases are alive and 28.7 per cent. are well from two to eight years after discharge.

III.—RESULTS OBTAINED IN FIFTEEN HUNDRED CASES DISCHARGED FROM TWO TO EIGHTEEN YEARS AGO.

The number of cases discharged from the Adirondack Cottage Sanitarium until two years ago was 1,500. Of these 366 (24.4 per cent.) were incipient, 778 (51.8 per cent.) were advanced, 343 ((22.8 per cent.) were far advanced, 2 cases were doubtful and 11 cases had incomplete records.

A.—*Incipient Cases.*—The 366 incipient cases were discharged as follows: Apparently cured, 245 (67 per cent.); arrested, 83; improved, 29; unimproved, 8. At the present time 170 (46 per cent.) are well; 13 are in a state of arrest; 14 have relapsed; 7 are chronic; 54 are dead; 108 are untraced. Of the 245 cases apparently cured 131 are well, while 30 of the 83 arrested cases, 9 of the 29 improved cases and none of the unimproved cases are well. Twenty-two of the apparently cured cases are dead; 16 of the arrested, 10 of the improved, 6 of the 8 unimproved cases are dead. The untraced cases are as follows: Apparently cured, 75; arrested, 23; improved, 8; unimproved, 2.

B.—*Advanced Cases.*—The 778 advanced cases were discharged as follows: Apparently cured, 90 (11.5 per cent.); arrested, 338; improved, 261; unimproved, 78; dead, 10. At the present time 151 (19 per cent.) are well; 51 arrested; 27 relapsed; 39 chronic; 295 (38 per cent.) dead; 215 untraced. Of the 90 apparently cured cases 54 are well, while 80 of the 338 arrested, 16 of the 261 improved and 1 of the 78 unimproved are well. Nine of the apparently cured cases are dead; 106 of the arrested; 118 of the improved, and 52 of the unimproved. The untraced cases are as follows: Apparently cured, 21; arrested, 71; improved, 100; unimproved, 22.

C.—*Far Advanced.*—The 343 far advanced cases were discharged as follows: Arrested, 51; improved, 116; unimproved, 152; dead, 24. At the present time 6 (1.7 per cent.) of these are well; 5 arrested; 3 relapsed; 9 chronic; 220 dead, and 100 untraced. The cases that are well at present are as follows: Arrested, 2; improved, 1; unimproved, 3. Twenty-eight of the arrested cases are dead; 63 of the improved, and 45 of the unimproved.

SUMMARY OF RESULTS IN FIFTEEN HUNDRED CASES.

In all, 497 (33 per cent.) cases are alive; 569 (38 per cent.) are dead, and 434 (29 per cent.) are untraced. Of the 497 patients that are alive 329 (22 per cent.) are well; 69 (4.6 per cent.) are arrested; 44 (3 per cent.) relapsed; 55 (3.7 per cent.) are chronic.

If we deduct 434 untraced cases we have left 1,066 cases which have been traced. Of these 31 per cent. are well; 6.5 per cent. are arrested; 4 per cent. have relapsed; 5.2 are chronic; 53.3 per cent. are dead. Deducting from the number of incipient cases those that have been untraced we find that there are left 258 cases. Of these 66 per cent. are well and 21 per cent. are dead. Of the 563 advanced cases which have been traced 28.6 per cent. are well and 52 per cent. are dead; while of the 235 far advanced cases which have been traced 2.5 per cent. are well and 90 per cent. are dead. It must be remembered, however, that these figures are only approximately correct, as no doubt more of the untraced cases are dead than these figures would indicate.‡

Clinical Reports.

A CASE OF NEURITIS OF THE RIGHT INFERIOR DENTAL NERVE

INCIDENT ON FORWARD DISLOCATION OF THE MANDIBLE OF THREE YEARS' STANDING.*

GEORGE A. MOLEEN, PH.G., M.D.
DENVER.

Aside from its rarity, the following case will illustrate the importance of a clear history and complete examination even in such a simple malady as facial neuralgia. I acknowledge my indebtedness to Drs. Packard and Silverstein for their prompt care and treatment of what seemed to be the cause.

Mrs. L. K., aged 49, born in Lebanon, Pa., has been in Colorado three years and did not come for her health; occupation housewife. First seen Feb. 7, 1903.

Family History.—Parents born in Pennsylvania; mother died of la grippe, father from dropsy. There were fourteen in the family, of whom five sisters and two brothers are living, the remainder are dead from various irrelevant causes. Tuberculosis, other chronic diseases, insanity and nervous diseases are denied.

Past History.—Of the exanthemata she had diphtheria at 9; measles at 22; denies scarlet fever; has had no sequelæ nor has she at any time complained of aural discharge, dizziness or vomiting. Menstrual history good; climacteric six months ago. When young she complained considerably of toothache, and neuralgia was suggested. Shortly after her arrival in Colorado she began to have paroxysmal pain confined to the right side of face, which seemed to originate, according to her localization, about the right lower bicuspid. This was drawn without relief, and after several medical and dental examinations the lowers were drawn to no purpose, until finally, on the advice of a physician, all her teeth, upper and lower, were removed in April, 1902, without modifying her symptoms.

Present State.—She has slept little for three months past, on account of pain. She says sedatives have given but little relief. The paroxysms come on at varying intervals of from 3 to 10 or 15 minutes, and seem to be excited by movement of the jaw, as in eating or talking, and can be excited by forcibly depressing the jaw. They sometimes begin in the ear and at others in the alveolar process. During the paroxysm the face becomes pinched, the right side flushed, and in severe attacks perspires slightly on the right side only. The pupil of the right eye is seen to dilate when the eye is held open and her hands restrained. Between paroxysms she becomes quiet,

‡ Since the above was written 5 of the untraced cases have been found to be alive, making 502 cases alive. In 10 cases death was due to other causes than tuberculosis.

* Read before the Rocky Mountain Interstate Medical Association, Salt Lake City, 1903.

though she complains of prickling of the right side of the face and of numbness and tingling on the right side of tongue. Sometimes there is a roaring in the right ear and a burning sensation in the right nostril. She has been partially deaf for some time and can be made to hear with difficulty, though more readily in the right ear.

Examination.—Feb. 7 and 10, 1903. Well-developed German woman, with drawn, careworn, though anxious, expression. All voluntary and co-ordinate motion normal and equal. Reflexes normal and equal and there is no response on tapping the masseter. Tongue is protruded in the median line, without tremor.

Sensory phenomena are in the main normal throughout the body, though she has impaired tactile sensibility with hyperalgesia on right side of face, the outline of which is as follows: Beginning at the external angular process extending upward to about the bregma, then downward and apparently dividing the ear—i. e., the tragus is more hyperalgesic than the concha and pinna—continuing downward to about one-half inch below the angle of lower jaw and forward to about the median line. Touching the skin at this area is not perceived as readily as on the opposite, and when perceived is painful. Pressure over the mental foramen causes severe pain and sometimes excites a paroxysm, the same being true at the infra-orbital opening. The supra-orbital is seemingly no more sensitive on one side than on the other. The submaxillary gland is also very tender and excites an attack readily. The mucous membrane of the right nostril, as well as the same side of the tongue, was markedly hyperesthetic.

Special Senses.—Salt placed on the right half of the tongue in the usual manner was met by immediate signal, but the tongue was washed and wiped, avoiding the left side, without allowing her to withdraw it, and she was unable to recognize and name the substance, even after several attempts with sugar, vinegar, etc.; near the base of the tongue, however, i. e., at about the anterior pillar, she recognized readily. Taste was present throughout the entire left side of the tongue. When asked why she signaled, she stated that she felt it as rough and thought she could taste it, but it was the pain she perceived. There can be no evidence of interference with smell detected.

Diagnosis.—The foregoing was strongly indicative of some mischief along the two lower divisions of the fifth nerve, and especially the third, and that it was undoubtedly irritative in character, a cause was consequently sought.

It was noticed that on depression of the lower jaw the condyle became quite prominent on the left side of the face, about three-quarters of an inch in front of and slightly below the external auditory canal. The right side revealed a corresponding depression, the jaw then rotated laterally and with considerable force, and by examination it was found that when depressed the internal pterygoid muscle was in a state of tonic contraction.

It then seemed but fair to assume that the condyle of the right side was irritating the inferior maxillary nerve at or about the site of the otic ganglion, which assumption was cleared on a study of its communications and branches, viz.:

The second division was affected through the connection by means of the vidian and petrosal, with Meckel's ganglion.

The sympathetic connection afforded an explanation of the flushing, sweating and pupillary symptoms.

The branch of the tensor tympani explained the increased hearing on the affected side.

The chorda tympani accounted for the loss of taste in the anterior portion of the same side of tongue.

It will be seen that the area of the first division was exempt.

Treatment.—Just how long the displacement had existed, or when it occurred, could not be learned, and the patient was even ignorant of its existence.

On account of the probable filling of the glenoid cavity by fibrous tissue a brace was advised, which would constantly exert an upward and backward pressure on the chin and still allow movement of the jaw, also with spring compresses to avoid the lateral movement of the condyles. She was accordingly referred with the above suggestions. A brace was devised which met the indication, and iodids and small doses of mercury given for a time.

Course.—After 4 or 5 days the pain began to subside and in about 10 days disappeared entirely. The sense of taste returned rapidly and the hearing on the affected side diminished until equal to that of the other side. She continued wearing the brace until about June 22, when she developed pain in the tongue and was unable to protrude the organ. Whether it was due to irritation of the hypoglossal by the chin rest or not I can not say, though it disappeared in two or three days after removal of the brace.

About July 1, having removed the brace, she began to experience very severe paroxysms of pain, which she described as boring in character, and localized constantly at a point a little below the condyle of the same side. The attacks were therefore quite different from her former ones, there being no area of hyperalgesia, nor was the tenderness of the mental foramen as marked. There was no swelling or tenderness along the process at this time.

The possibility of neuroma at or about the point of irritation was considered, and Drs. Hopkins and Freeman were consulted regarding the advisability of operative interference,

The brace in position.

which now seemed to be the only means of affording her relief. During this time she was given three grains of codein in divided doses, in the course of three hours, which gave her more relief than three-eighth grain morphin. A small cyst was noticed at the angle of the jaw, internally, and opened without perceptibly influencing the symptoms.

The brace was reapplied and adjusted to increase the pressure on the chin, and at first had little effect. The potassium iodid and mercury (red iodid 1/50 grain) were resumed.

The pain gradually left her and at the present time she scarcely notices it. The brace has been kept in place steadily since, and she is still taking the iodids, mercury and codein, while enjoying her escape from the surgeon for the present.

DEATH BY LIGHTNING.

B. KELLY, M.D.

CLIO, IOWA.

A powerful man, weighing 212 pounds, 36 years old, was struck by lightning. In about 10 or 15 minutes I found him deeply cyanosed, skin relaxed and cool and the heart beating feebly, but there was no visible respiration. I gave him hypodermic injections of strychnin, whisky and finally the normal salt solution, keeping up artificial respiration for ten hours, when the heart failed. The face brightened slightly for a few moments under the artificial respiration and the heart at short periods beat stronger, but no farther reaction was obtained, the temperature steadily falling.

Finding literature scarce on the subject I will be glad to have some one state what would have been the prospects for a better result by the use of an electric battery.

MENDEL'S LAWS AND RECENT ANIMAL EXPERIMENTS IN HYBRIDIZATION.

During the last decade perhaps no other set of scientific papers has called forth more discussion than have Mendel's memoirs on experiments in cross-fertilization of plants, which were briefly reviewed in a recent issue of THE JOURNAL.[1] Several experimenters have recently published their results obtained by cross-breeding animals, and earlier experiments have been reviewed in the light of Mendel's laws. The conclusions do not agree, however, as there is a difference in the interpretation of the results by different authorities. In 1885 Crampe published his results from crossing gray wild mice with albino mice, and these results are especially interesting because he was at that time not familiar with Mendel's laws. All the offspring coming from this cross were gray, the white being shut out (recessive). In the offspring from these hybrids the recessive characters reappeared. That is, there were 27.8 per cent. albinos and 72.2 per cent. colored mice. This is in close accord with Mendel's laws, as according to them there should be about 25 per cent. of albinos in this generation.

Von Guaita crossed Japanese waltzing mice with albinos and got hybrids resembling wild house-mice, both in color and behavior. There seems to have been here a reversion to the ancestral type. No albinos were found among the hybrids. From these hybrids, however, he got 14 albinos (31 per cent.) and 30 colored mice, some gray, some black, and some spotted. The albinism seems to have been recessive, in the Mendelian sense, but the variety of colors among the others is not in accord with Mendel's principles.

Cuénot crossed gray house-mice with white mice and invariably got gray hybrids, the white being recessive. These hybrids were mated and produced 270 young, 26.6 per cent. of which were albinos and 73.4 per cent. gray. The albinos produced only albinos in the succeeding generations. According to Mendel's laws, one-third of the grays should produce gray offspring and two-thirds of them should produce albinos and grays in the average proportion of one to three. It is not easy to select the constant grays from the hybrids and mate only hybrids, but Cuénot believes that the results are in close agreement with the demands of the law. From several matings of what he believes to have been hybrids coming from the first generation of hybrids he got 219 young, 21 per cent. of which were albinos and 74 per cent. gray.

Darbyshire mated Japanese waltzing mice with albinos, and the offspring, which represent 203 individuals, are all colored, but some of these are quite different from the Japanese waltzing mouse. There are no albinos, and none of these hybrids waltzes. He now mated some of these hybrids and got 37 offspring, 9 of which were albinos, approximately 25 per cent. Eight mice of this generation waltzed. In crossing albinos of the first generation of hybrids he got 39 albinos, 31 wild colored, 15 black and 3 yellow mice among the offspring. That is to say, there was a fairly sharp segregation into albinos and wild colored mice. According to Mendel's laws, there should be about 50 per cent. of albinos. The color of the eyes, however, does not follow Mendel's laws. Both the albinos and the Japanese waltzing mice have pink eyes, while the hybrids have dark eyes. If the pink eyes were recessive they should remain constant when both parents have pink eyes, and if they are dominant they should also be constant here.

Lastly may be mentioned Wood's records in hybridization of rabbits. This work was undertaken with a view of testing Galton's law of inheritance which may be stated here: "One-half of the heritage of any generation is derived from the parents, one-fourth from the grandparents, one-eighth from the great-grandparents, etc." Wood had black rabbits which were considered to be hybrids, and on mating them got 133 offspring, 21 per cent. of which were white. In mating black hybrids with albinos he got 40.3 per cent. albinos. In both of these experiments there were not quite enough albinos according to Mendel's laws. In mating albinos which came from black parents the offspring were always white. This result agrees with Mendel's laws, but it is entirely out of harmony with Galton's law.

It is seen from these experiments that most of the results agree fairly well with Mendel's laws, but there appear to be some exceptions. At present, however, the experiments are too few to draw positive conclusions from them, and as rabbits and mice are very complex organisms, it is possible that errors have crept in. It is left for the future, therefore, to determine how closely we can predict the characters of the offspring when the characters of both parents are known.

TUBERCULOSIS IN INDIA FAVORS KOCH'S VIEWS.

The problem of tuberculosis will not be worked out in one country or in one climate, and any one who bases his conclusions on the contracted view of his own personal experience is liable to be mistaken. There are many advantages in studying the disease under all conditions, requiring ranges of temperature, social and dietary customs, etc., which are not to be found in any one district or country.

The recent report of the health officer of Calcutta is somewhat to the point. As it appears from an abstract in the *Indian Medical Gazette,* tuberculosis is statis-

tically put down as furnishing 6.4 per cent. of the adult deaths in that city. The health officer, Dr. Cook, thinks that this is far too low a figure, and bases his opinion on several facts which seem to give it standing. For example, in the Medical College Hospital, Calcutta, 966 consecutive postmortems showed 13.4 per cent. of deaths due to pulmonary tuberculosis and 3.6 per cent. to other forms of tuberculosis. There are, moreover, he says, a large proportion of cases of tuberculosis that are not recognized. Calcutta is full of irregular practitioners of every sort, qualified and unqualified, and an immense number of tuberculous cases are registered under the names of dysentery, malaria, asthma, etc. Such cases come within the experience of every consultant physician.

It is well known that the tropics are no more exempt from tuberculosis than the temperate countries, but there are certain special phases that can be observed there, especially in a country like India, where religious and social customs have an important influence. Dr. Cook is inclined to think from his own Indian experience that there is some basis for Koch's utterances as regards the differences between bovine and human tuberculosis. The Indian experience shows that the Hindoos who eat no beef, who practically sterilize all the milk and cow-products they use, are no more exempt from tuberculosis than the Christian and Mohammedans in their midst. Another point raised is the comparative infrequency of tuberculosis in Indian children. This may possibly be accounted for by the late period of weaning and the almost universal practice of maternal nursing. Tuberculosis in India is, as a rule, a disease of adult life, and Dr. Cook seems to think that its propagation is almost always by contagion through sputum. The editor of the *Indian Medical Gazette* remarks that tuberculosis in all its forms is less frequent, according to his own observation, among native children than among those of the Eurasians or Europeans.

So far, Indian testimony seems to be in favor of the contagiousness of the disease and against Behring's theory of infant infection, though it is not, of course, conclusive, as there are too many elements to be considered. A thorough cosmopolitan study of the disease under all circumstances will assuredly be a valuable aid to the elucidation of its problems.

THE ARTIFICIAL CULTIVATION OF PATHOGENIC PROTOZOA.

Progress in the biologic sciences relating to medicine is dependent in large measure on special technical methods. This fact is particularly well illustrated by the history of bacteriology. The science of modern bacteriology is the direct outgrowth of the development, especially by Koch, of suitable media, more particularly solid media, on which bacteria will grow and multiply in a characteristic manner and in such form that it is possible to secure pure growths. Only in this way could it be possible to study adequately the cultural and other biologic peculiarities of bacteria and to obtain pathogenic bacteria in such form as to be able to subject them to various conditions and manipulations essential to investigations into the complex problems of immunity. The ingenuity required to secure pure growths on artificial media of some pathogenic bacteria is illustrated well in the case of the bacillus of tuberculosis, the gonococcus and the bacillus of influenza. Thus growth of the latter two is favored specially by the presence of certain constituents of human blood. And in spite of innumerable efforts, the peculiar requirements necessary to induce the bacillus of leprosy to grow on artificial media have not yet been discovered. This bacillus multiplies freely in the lesions of human leprosy, where it is readily demonstrable by special staining methods, but to this day pure cultures of the lepra bacillus have probably not been obtained. There are many diseases of undoubted infectious nature the unknown as well as the morphologically demonstrable pathogenic agents of which, so far as we know, are uncultivable with the methods now at hand.

Since it became established that certain diseases of man and animals were intimately associated with the presence of protozoa, which there was full reason to believe were specifically pathogenic, investigators have exercised the greatest ingenuity in order to devise suitable methods for their artificial growth. Success at last has crowned the efforts of Novy and McNeal, who have found that the trypanosoma of rats and of the tsetse-fly disease may be grown in the condensation fluid of agar mixed with rabbit's defibrinated blood—a really quite simple method. This being done, it was easy to take the next step, namely, to demonstrate the pathogenic powers of these trypanosomes by the injection of pure cultures. As indicated in their report in this issue of THE JOURNAL,[1] experiments in immunization are now feasible. The Ann Arbor investigators are therefore entitled to hearty congratulation on having succeeded in opening the way for the successful study of pathogenic protozoa in pure growths under artificial conditions along the same lines that have yielded such brilliant results in that other department of microbiology, namely, bacteriology.

May this prove to be but the beginning of a series of successful cultivations of microparasites of animal origin. Perchance we shall learn before long that colonies of protozoa can be grown on solid media as well. In bacteriology artificial cultures in liquid media preceded the development of the methods of cultivation on solid media, and it may well be that this will turn out to be the case with the animal microparasites also.

THE SELF-REPARATIVE POWER OF THE SPINAL CORD.

Some time ago we noticed editorially in THE JOURNAL[2] a remarkable case in a Philadelphia hospital in

1. See page 1266.
2. THE JOURNAL A. M. A., vol. xxxviii, p. 1626, June 21, 1902.

which, owing to traumatism and destruction of the cord, about three-quarters of an inch was resected and united again by sutures with the result of a partial restoration of function. There has been, so far as we know, no more recent report regarding the progress of this case in medical publications, though we have seen such notices in the daily press.

An almost equally remarkable case has just been reported by Dr. C. Harvey Rodi[3] of Calumet, Mich.: The patient was injured by a falling rock, and was operated on three hours after the injury. There was complete paralysis below the seat of fracture, and dislocation and fracture at the junction of the tenth and eleventh dorsal vertebræ. The ligamentous attachment of the tenth and eleventh spinous processes was severed and the arches separated so widely that the spinal canal was laid open and the cord exposed. The body of one of these vertebræ was fractured, and the cord was seen to be entirely severed save a filament about the size of a pin connecting the two parts which were separated about an inch. It is not stated that the cord was sutured, but portions of the articular process of the tenth and eleventh vertebræ were removed with a chisel to assist in reducing the dislocation and with a view to bony union. The wound was closed with silkworm gut, and a few strands inserted for drainage and a plaster jacket applied. The next day, it is reported, there was sensation a little below the pelvis; a week later sensation existed about the ankles, but paralysis continued for some time. A large deep sacral bed-sore appeared, there was incontinence of urine and of feces with cystitis; the patient nevertheless began to improve very rapidly, and is now—a year later—in control of both the sphincters and can go around on crutches. He claims to be getting stronger in his legs every day and looks forward to complete recovery. In this case the little band of spinal tissue seems to have acted like the catgut connection which has sometimes been made in widely-divided nerve suture, and as the route along which regenerated tissues can travel. It is hard to say what the actual condition of the cord is at the present time, but there certainly must have been a considerable restoration of structure to account for the restoration of function so far as it has progressed.

The case is well worth watching. Dr. Rodi had three local physicians examine the case at the time of the operation beside two medical students, and there seems to be no reasonable ground for questioning the facts. Our ideas not only as to regeneration of the nerves but also of the nerve centers seem likely to be somewhat revolutionized if such cases as this become very common.

3. The Journal of the Michigan State Medical Society for November.

ONE WAY OF DOING IT.

Our British contemporary, the *Medical Press and Circular,* editorially notices a peculiar method of revenging insults to the medical profession which, while we can not commend it, is perhaps somewhat excusable under the circumstances. In an Irish community certain of the public authorities had given out gratuitous and highly offensive utterances in regard to the medical profession in the district. The local branch of the British Medical Association made, our confrère says, an inarticulate but very effective reply. They did not resolve to boycott or refuse their medical services to the offending parties, but made a rule that special fees should be charged them and their families. The surest way to touch most people is through their pockets, and our contemporary hopes it will be effective in this case.

A REDISCOVERED TEST FOR MUMPS.

It is rather remarkable how well-known facts come to be rediscovered. There is probably no general practitioner of any experience in this country who has not heard of the diagnostic test for mumps—eating a pickle. In fact, it may be considered as a matter of universal knowledge. It seems, however, to have been only recently discovered abroad. A French physician reports in a Paris medical journal the value of vinegar or acetic acid as an early test for mumps and the directions are much the same practically as those in family domestic use in this country. The patient must swallow after the application of vinegar or acid, which causes a painful reflex secretion of saliva—the same old well-known phenomenon. That this idea is a new one in Great Britain also is apparently evidenced by the fact that our esteemed contemporary, the *British Medical Journal,* considered the article of sufficient importance to include it in its epitome of current medical literature in its issue of October 31.

THE DE NOVO ORIGIN OF INFECTIONS.

In a recent number of the *Lancet,*[1] Dr. H. Charlton Bastian advocates the *de novo* origin of a number of diseases considered by us as specially typical of bacterial infection. He bases his arguments on some experiments, made as far back as 1882 and 1884, and even earlier, of the production of so-called septicemias in the rabbit by the injection of putrid blood. One of these, the so-called Davaine septicemia, was undoubtedly a true septicemia, as we now understand the word. The other, Pasteur's septicemia, would probably be now more commonly recognized as a bacterial intoxication. The experiments to which he refers, however, can be usually assumed to be accounted for according to modern ideas of bacterial pathology, and his arguments based on these will not be held, by the modern pathologist, to carry much weight. He admits that it is not absolutely necessary to assume that bacteria can be produced *de novo,* but that they can be modifications of pre-existing and less virulent germs excited into active virulence by some special irritation. This is a modern view to some extent, and we may deem it possible. When, however, it is applied to such disorders as tuberculosis and leprosy, as in Dr. Bastian's article, our faith in his views is somewhat shaken. He seems to be positive, as he says when noticing Behring's recently enunciated

1. October 31.

opinions as to the latency of tubercle germs: "I, on the other hand, have proved the possibility of their *de novo* origin." Dr. Bastian's reputation as a scientific physician and an investigator is well established, but his earlier opinions in regard to the beginnings of life have long since been discredited. It would seem that he still holds to them, at least in a modified form. There is no necessity for believing that every inflammation or irritation is of bacterial origin, but that certain recognized disorders like consumption, leprosy, etc., are thus originated seems to be as much beyond question at the present time as any scientific fact. Dr. Bastian's paper is a sort of curiosity in its way, not only from what it really says, but also from what it infers; yet it will not, we think, give rise to any very serious questioning of the modern accepted views.

THE KAISER'S CASE.

The latest official reports from Germany, especially the details furnished by the operator, Dr. Moritz Schmidt, seem to give authoritative and trustworthy details as to the character of the growth that was removed from the throat of the German Emperor two weeks ago. Contrary to what was at first described, it is now announced that the polypus had no stem, as is usually the case, but spread itself over the surface, and especially over the free margin of the left vocal cord. For this reason the operation was more complicated than with an ordinary laryngeal polypus. The operation had to be done by a formal excision through surrounding tissues in order to enable the operator to obtain a grasp of the polypoid growth for complete removal. Perhaps the most discouraging part of the report is the fact that the entire left vocal cord was inflamed and reddish before the operation, and it is therefore expected that the return to normal conditions will require a rather prolonged period of convalescence. The fact that the so-called polypus was not pedunculated but sessile, would seem to indicate that it might be a neoplasm of infiltrating type, and in a position that is so prone to malignant degeneration as the larynx, this is not an encouraging feature of the case. The presence of some inflammatory reaction for a considerable period, and the fact that the scar of an operation of this kind is liable of itself to be a source of chronic irritation because of contractile tendencies inevitable in the new-formed tissues that will cover the defect, increases the possibilities of future malignant degeneration. When to this is added the discouraging factors in the Kaiser's personal history, the death of both father and mother from malignant disease, it can readily be understood why the matter causes serious apprehension in many minds. Professor Orth's very positive declaration of the non-malignancy of the growth was somewhat tempered by the fact that he considered certain elements in the tissues examined by him deserving of further investigation. While we certainly accept the statements of those who have charge of the case, as far as they go, and can not feel justified in taking a pessimistic view of the matter, it is well to remember at this time that on three separate occasions Orth's great predecessor, Virchow, was asked to examine portions of tissue removed from the throat of the Kaiser's late father, and on each occasion failed to find any sign of malignancy in them; and we all remember the outcome. We sincerely hope that these unfavorable possibilities—for they must at this time be regarded as such, and not as probabilities—may never be realized, for the German Emperor is one of the great moral forces in our generation.

DIABETIC FLOUR.

It has long been known from the analyses of Woods, Atwater and others that a number of so-called diabetic flours are not what they are claimed to be, and are only misleading and often injurious substitutes for the ordinary bread-making materials. It seems that some German and French manufacturers have succeeded in producing a gluten flour suitable for bread making, and similarly certain British makers have also approximately succeeded. It would appear that we have been less fortunate in this country; the New Hampshire State Board of Health has recently collected specimens of all the diabetic and gluten flours so advertised that were obtainable, and publish in their October report the results of an analysis of these samples. Out of 13 samples 7 had very little less than the average amount of starch, and only 2 samples were comparatively free from it. Neither of these two, however, were suitable for bread making, but were rather a sort of breakfast food or material for combination with almonds, etc., in preparing biscuits. A few others had a rather notably reduced amount of starch, and one, the soja bean meal, would be valuable as a substitute if it were possible to make a palatable bread from it. The results seem to show that many of the so-called diabetic foods, or gluten flours, are very little different from the whole wheat or graham flours, and have very little less starch than the ordinary white wheat flour. Some of the more highly-recommended and widely-advertised diabetic flours, the New Hampshire analyst says, "consist solely of whole wheat flour and by reckless misstatement and deliberate fraud are sold at enormous prices as a cure for diabetes." In a few cases the analyses show that the manufacturers have evidently tried with more or less success to produce a flour low in starch, and the judicious use of their products might be beneficial, but in any case the amount of starch present is high, and the flour must be used sparingly. The same results can be equally well obtained from diminishing the amount of ordinary bread material. There is a great deal of money in this manufacture, and the temptation for misrepresentation is great. One of the most disreputable methods employed is that noted in a recent British contemporary[1] where diabetic-flour manufacturers sent circulars to druggists all over Great Britain offering them 5 shillings for the address of every diabetic patient in their knowledge and thus endeavored to obtain surreptitiously and at the violation of professional confidence a means of advertising their wares. The concern thus acting is the Diabetes Flour Company of London, and its name should be remembered in case they attempt to introduce their products in this country.

1. Med. Press and Circular, Nov. 4, 1903.

Medical News.

CALIFORNIA.

More Bubonic Plague.—Three more deaths from bubonic plague occurred in San Francisco, October 20, 23 and 24.

Physician Aeronaut.—Dr. August A. Greth, San Francisco, has made a successful trip over San Francisco in a dirigible airship constructed by himself.

Smallpox.—In the Ophir district, Auburn, five cases have been discovered in one family.——During October 8 cases of so-called varioloid were reported in Sacramento.

To Clean Chinatown.—Mayor Schmitz of San Francisco has signed the ordinance passed by the board of supervisors appropriating $5,000 from the "Urgent Necessity Fund" to continue the work of thoroughly cleaning Chinatown and endeavoring to put that part of the city in sanitary condition.

Personal.—Dr. Ernest W. Fleming, Los Angeles, has returned from Europe.——Dr. and Mrs. Joseph Kurtz and daughter, Los Angeles, have returned after nearly a year abroad.——Dr. William F. Snow, assistant professor of hygiene at Leland Stanford University, has been made associate professor in the same department.——Dr. Aloysius P. O'Brien, San Francisco, has been commissioned colonel and surgeon-general of California.——Dr. Orra C. Hyde, Oakland, has been made resident physician in the St. Quentin prison.——Dr. J. Raymond Hurley, late U. S. M.-H. and P. H. Service, has accepted the position of surgeon on the Pacific Mail Steamship Company's steamer *American Maru*.——Dr. Melville M. Shearer, Santa Rosa, has been appointed a member of the advisory board recently formed to draft sanitary laws to be introduced at the next session of the legislature.——Dr. Ira B. Ladd, Stockton, has been re-elected physician of San Joaquin County.

COLORADO.

Deaths in the State.—During September 782 deaths and 22 still-births were reported, an annual mortality rate of 10.47 per 1,000, excluding still-births. Typhoid fever caused 51 deaths, diphtheria 14, and scarlet fever 5.

Communicable Diseases.—During September 123 cases of diphtheria were reported in the state, an increase of 14 cases over the preceding month; 62 cases of scarlet fever, an increase of 28 cases; 40 of smallpox, a decrease of 3 cases, and 386 cases of typhoid fever, an increase of 183 cases.

A Criminal Sentenced.—Dr. S. D. Van Meter, secretary of the Colorado State Board of Medical Examiners, informs us that Edward Reitzel, ex-convict of Pontiac Reformatory, alias Dr. George A. Elliott, alias George E. Cook, registered in Colorado by a stolen diploma from the Toronto University, 1896, was convicted of criminal abortion and sentenced November 14 to three years in the Colorado penitentiary. The details of this man's history, with his photograph, were published in THE JOURNAL, Jan. 3, 1903, page 42. Dr. Van Meter says further: "After skipping his bond in Colorado he changed the Elliott diploma to read George E. Cook, and registered it in Oklahoma. Accompanying it was an affidavit purporting to be from Dr. John B. Murphy, but which is a forgery throughout, the signature and all being in the handwriting of Reitzel's third wife, nee Mary Etta Inman. The real Dr. Elliott is practicing in Leamington, Ontario."

ILLINOIS.

Diphtheria Closes Schools.—A Decatur telegram reports that diphtheria has caused the closing of four schools in Long Creek and Mount Zion townships.

Personal.—Dr. Lee Smith has been elected chief of the medical staff of St. Joseph's Hospital, Bloomington, vice Dr. Charles R. Parke, removed from the city.——Dr. Ulric A. Bedard, Ste. Anne, has returned to America after a stay of three years in Paris.

Physician Breaks Laws.—At the semi-annual meeting of the Livingston County (Ill.) Medical Society, held in Pontiac, November 6, the censors reported that Dr. William L. Rabe, Dwight, had pleaded guilty to the charge of selling liquor to minors and he was accordingly expelled from the society.

Asylum Attendants Go Free.—The grand jury at Peoria found no indictment against the two asylum attendants accused of the murder of Thomas Hartley, the insane patient. The jury said they believed it would be impossible to show that the men were not defending themselves since no one saw the struggle except the participants.

Smallpox.—Ridgway has 8 cases.——The disease has appeared at Kewanee.——The quarantine of Joliet against Lemont was lifted November 11. Disease has not disappeared, but every precaution against its spread is being observed.——From 70 to 80 cases are said to exist in St. Clair County.——South Wilmington reports 6 cases.

State Charity Report.—The bulletin of the State Board of Charities for three months ended September 30 was issued November 10. The average number of inmates during the quarter was 10,826. The gross per capita cost of maintenance was $40.42 and the net per capita cost to the state $34.65. At the end of the quarter there was $4,710,924 27 in the state treasury to the credit of the institutions. The best record was made by the Illinois Eastern Hospital, Kankakee, where the net per capita cost for the quarter was only $29.21.

Chicago.

Presbyterian Hospital Concert.—The fifth annual concert for the benefit of this hospital on November 12 was well attended and netted about $7,500.

New Maternity.—The "Mercy Maternity" has just been completed as an adjunct to Mercy Hospital. The building is detached, and is under the charge of Dr. Joseph B. De Lee.

Deaths of the Week.—The deaths for the week ended November 14 were 484, equivalent to an annual mortality per 1,000 of 13.38, two deaths less than for the corresponding week of last year, and eight deaths more than for the previous week.

Gift to Wesley Hospital.—Rev. R. D. Sheppard of Evanston has offered $35,000 to Wesley Hospital toward paying off its indebtedness, provided the remainder, $25,000, is raised in two years. The trustees accepted the conditions and report that $17,000 of the necessary amount is already in sight.

Increased Mortality.—During the last thirteen years, 1890-1902 inclusive, the mortality from nephritis, heart disease and pneumonia has increased over that of the thirteen years, 1877-1890 inclusive, in the following ratios: Heart disease, 48 per cent.; pneumonia, 53 per cent., nephritis, 87 per cent.

Northwestern Faculty Changes.—At the meeting of the board of trustees of the Northwestern University, November 17, Dr. Charles L. Mix was elected professor of physical diagnosis to fill the vacancy left by the resignation of Dr. George W. Webster; Dr. Fred Menge was elected assistant professor of laryngology and rhinology, and Dr. William A. Mann was elected assistant clinical professor of ophthalmology and otology.

MARYLAND.

Personal.—Dr. Washington C. Claude, chief of staff of the Annapolis Emergency Hospital, has resigned.

Election of Officers.—The Frederick County Medical Society elected the following officers for the ensuing year: President, Dr. C. W. Goldsborough; vice-presidents, Drs. David M. Devilbiss and E. L. Beckley; secretary, Dr. Ira J. McCurdy; treasurer, Dr. William C. Johnson; librarian, Dr. Harvey F. Gitzendanner.

Emergency Hospital.—The Frederick County Medical Society's new hospital building will be formally opened December 1, with 25 beds. A board of trustees consisting of a number of physicians, with Dr. William H. Wagner as chairman, has been elected to manage the institution, which will be known as "The Emergency Hospital of Frederick County." Dr. Thomas Cullen, Baltimore, held a clinic before the society November 11, and read a paper.

Baltimore.

Deaths of the Week.—There were 190 deaths for the week ended November 14, five only being from typhoid fever.

Personal.—Dr. A. L. Frank has been elected president of the Hebrew Orphan Asylum and Hospital, vice Menka Friedman, deceased.

Another Ginger Death.—A case of death from wood alcohol poisoning was reported here on November 7 in a woman who had taken several doses of Jamaica ginger for "internal trouble." The attending physician's certificate was confirmed, on examination, by the coroner.

Tuberculosis Exposition.—Preparations are being consummated for the tuberculosis exposition, to be held here in January, under the combined auspices of the tuberculosis commission, the State Board of Health, and the Maryland Public Health Association. Details are in charge of Dr. W. S. Thayer, president of the commission; Mr. John M. Glen, secretary; Dr. John S. Fulton, secretary of the State Board of Health, and Dr. Marshall L. Price. Dr. Henry B. Jacobs has been elected chairman, and 250 prominent professional men and laymen have been asked to act as an advisory committee. A series of

lectures will be given, the object of which will be to present the extent and effects of the disease in a striking manner. The prevalence of the disease, its incidence on certain occupations and trades, and the various hygienic and personal factors which influence its spread will be shown. The pathologic exhibit will be arranged to show the effects of the disease on the various organs. Tuberculosis in the lower animals will also be fully illustrated. One section of the exhibit will be devoted to the various appliances used in the treatment and cure of tuberculosis. Hospitals and sanatoria will be illustrated by means of plans, elevations, photographs, models and by tables illustrating the cost and results of treatment. A number of special appliances will be shown for open-air treatment, among them portable houses, tents and special sleeping devices. This exposition will be the first of its kind ever held, and already has aroused considerable interest among physicians in this country and abroad. Among the sanatoria exhibited will figure about 75 American institutions and about 30 from abroad, of the latter the largest contingent will be furnished by Germany, the remainder being from France, England, Switzerland, Austria and Norway. The largest exhibit of the statistical and economic sides of the question will be furnished by Maryland. The influence of the disease on the birth-rate and school attendance, and the public and private cost, will be shown by means of charts and diagrams.

OHIO.

Adds Obstetric Department.—The Cincinnati City Hospital has added a department of obstetrics to be under the charge of Drs. William H. Taylor and George M. Allen.

Diphtheria.—Schools in Troy have been closed because of diphtheria.——Out of 39 children at the Holy Family Orphanage, Cleveland, 15 are said to be ill with diphtheria.

Personal.—Dr. Christian R. Holmes has resigned from the commission appointed to build the new city hospital, Cincinnati. Dr. Byron Stanton was appointed to fill the vacancy.

Change City Physicians.—The twelve district physicians formerly in the employ of Cleveland have been replaced by six, and the salary of five has been increased to $600 per annum. The physician for the first district, on account of extra duties, has a salary of $1,000.

Room for More Patients.—The board of medical advisers of the Cincinnati City Hospital, on the advice of the chief of staff, have thrown open three wards previously used as nurses' quarters, and have secured a building near by, to be used exclusively as a nurses' home.

Smallpox.—There are said to be 15 cases at Folk Station on the Cadiz branch of the Panhandle Railway.——The State Board of Health has been notified of 20 cases at Alliance, 10 at Marion, and 8 or 10 at Columbus Grove.——Portsmouth has quarantined against the districts affected with smallpox.

Staff Physicians Elected.—The election of staff physicians for the Cincinnati City Hospital resulted as follows: Physicians—Drs. George A. Fackler, Joseph Eichberg, E. W. Mitchell, Oliver P. Holt; neurologists—Drs. H. H. Hoppe, Frank W. Langdon; surgeons—Drs. N. P. Dandridge, Joseph Ransohoff, E. W. Walker, John C. Oliver; orthopedic surgeons—Drs. A. H. Freiberg, C. E. Caldwell; dermatologists—Drs. A. Ravogli, C. S. Evans; laryngologists and aurists—Drs. S. E. Allen, J. W. Murphy; oculists—Drs. Robert Sattler, D. T. Vail; obstetricians—Drs. W. H. Taylor, G. M. Allen; gynecologists—Drs. Charles A. L. Reed, John M. Withrow, C. L. Bonifield, Sigmar Stark; pathologists—Drs. H. W. Bettmann, Arch 1. Carson; pediatrists—Drs. Allen G. Poole, B. Knox Rachford; neuropathologist—Dr. David I. Wolfstein; clinical pathological laboratory and museum—Drs. John E. Greiwe, director, William H. Crane, James R. Rowe, Carl Hiller, Alfred Friedlander, Horace J. Whitacre, Frank E. Fee; physician to the Branch Hospital—Dr. B. F. Lyle, assistant Dr. Cook; resident physician—Dr. John E. Stemler.

TENNESSEE.

College Opens.—Tennessee Medical College, Knoxville, opened for its fall session November 2.

Tribute to Dr. Mitchell.—Tributes were paid to the memory of the late Dr. Robert Wood Mitchell of Memphis in resolutions adopted by the Memphis and Shelby County Medical Society at a special meeting held November 3.

Society Elects Officers.—At the annual election of officers of the Greene County Medical Society, Dr. Claude P. Fox, Greeneville, was elected president; Dr. I. B. Brown, Moskeim, vice-president, and Dr. S. Walter Woodyard, Greeneville, secretary.

Knoxville Mortality High.—The report of the Knoxville Board of Health for October shows the highest death rate for that month since 1898. The deaths numbered 47, equivalent to an annual death rate of 14.10 per 1,000. Pneumonia heads the list, with tuberculosis a close second.

Personal.—Dr. Charles Brower, Nashville, has been seriously ill with septicemia resulting from an infected wound received during a surgical operation.——Dr. J. Sinclair Dye has been selected as city physician of Chattanooga, to assume office at the expiration of the term of Dr. Edward R. Wise, January 1, 1904.

Smallpox.—Robertson County has 23 cases and several points of exposure.——Lilly Bluff School, near Langford, has been closed on account of the disease.——The secretary of the State Board of Health fears that there will be a great deal of smallpox in East Tennessee this winter.——Cumberland County has its first case in two years.——In the Knoxville Isolation Hospital 100 cases are under treatment.

TEXAS.

Smallpox.—The health officer of Harrison County reports 13 cases of smallpox and 2 suspicious cases in the Harleston neighborhood in the western part of the county.——Marshall has two cases.

Portrait Presented to Health Department.—On request of Dr. Tabor, the family of the late Dr. Walter F. Blunt, who was connected with the state quarantine service for over a quarter of a century, has given a large well-framed crayon picture of the Doctor.

Yellow Fever Abating.—Dr. George R. Tabor, state health officer, reports the yellow-fever situation as follows:,

Actual conditions in Texas are as follows: About 700 cases, with 60 deaths in Laredo; 18 cases, 8 deaths in San Antonio, with no case reported in San Antonio for seven days; 5 cases, 2 deaths in Dewitt County.

These are the only places of infection in Texas, and it is a true statement of existing conditions. Two frosts have fallen in Bexar and Dewitt counties. Conditions are favorable in Bexar, and I apprehend no further cases. Cases in Dewitt County confined to one house, with no other house nearer than one mile. Disease is ended there. Laredo is well quarantined.

There is no danger whatever to people coming to Texas, as our quarantine will amply protect other sections of the state. We hope to be able to give San Antonio a clean bill of health within a few days. The state and federal governments are co-operating at Laredo, and hope to exterminate the infection there soon.

VIRGINIA.

The Seaboard Medical Association of Virginia and North Carolina will meet in Norfolk, December 15, 16 and 17.

Wage War Against Irregulars.—The Norfolk Medical Society, at its meeting, November 10, appointed a committee to investigate charges against illegal practitioners of the city.

Personal.—Dr. W. Armistead Gillis, Petersburg, has received an appointment in the laboratory of the Bureau of Medicine and Surgery, U. S. Navy.——Dr. George Walke Wallace, Norfolk, after a period of ill health, has resumed practice.——Dr. Charles G. Cannaday, Roanoke, has been presented with a gold-headed cane by the exhibitors at the Virginia Medical Society meeting.——Dr. Albert S. Priddy, Marion, has moved to Bristol, Tenn.——Dr. E. C. S. Taliaferro, Achilles, has returned from Europe and is practicing in Norfolk.

WASHINGTON.

Fire Destroys Hospital.—A fire which caused a loss of more than a million dollars at Aberdeen, Wash., destroyed two buildings of the Grays Harbor Hospital.

Physician Injured.—Dr. W. C. Pallister, local surgeon of the Northern Pacific Railway at Kennewick, jumped from a train in motion, and sustained serious contusions and wounds.

Typhoid at Yakima.—The State Board of Health, which has been investigating the typhoid fever situation at North Yakima, reports a deplorable sanitary condition of the city; that about 200 cases of the disease exist in the city and vicinity, and that the death-rate is high.

Still in the Dark Ages.—Colfax is said to be wrestling with the vaccination problem. The State Board of Health has issued an order that all school children be vaccinated. It is reported that many Colfax people resent the order, consider it unconstitutional and are raising funds to make a test case.

WEST VIRGINIA.

Quarantine Lifted.—The smallpox quarantine which closed the Broaddus Institute, Clarksburg, for nearly a month, was

lifted November 4. Two students had smallpox, and two or three others what was called varioloid.

Smallpox Rages.—Kenova and Ceredo have epidemics. In Ceredo there are 50 cases, with 4 deaths. Both towns are quarantined against by Huntington, Catlettsburg and Ashland. From November 2 to November 4, 7 new cases were reported in Kenova, and 12 new cases in Ceredo.

Hospital Opened.—The Davis Memorial Hospital, Elkins, built by the late Henry G. Davis and wife, at a cost of $85,000, as a memorial to their son, who was drowned off the coast of Africa, was opened October 8. Dr. William W. Golden is superintendent and surgeon-in-charge, Dr. M. S. Wilson assistant resident physician, and Drs. William Osler, Thomas S. Cullen, Louis McL. Tiffany, and Frank Martin, Baltimore, are on the consulting staff.

State Board of Health Speaks.—The State Board of Health, after summarizing the smallpox situation in the state, and noting the increase in mortality from 12 to 20 per cent., recommends vaccination and revaccination and the exclusion from school of children who have not been vaccinated or who have not fully recovered from infectious diseases. Superintendents of state institutions are directed to have all inmates and employes vaccinated and to admit persons only with the greatest precautions against infection.

WISCONSIN.

Smallpox in Indians.—Smallpox has broken out among the Winnebago Indians who are in camp near Portage.

All Have Registered.—Every physician in Douglas County has either passed the prescribed examination or has registered.

Loving Cup Presented.—At the recent meeting of the Central Wisconsin Medical Society at Janesville, Dr. Joseph B. Whiting of that city was presented with a silver loving cup by the society.

Opens Sanitarium for Children.—Dr. Mary E. Pogue has opened a sanitarium at Lake Geneva, Wis., for the treatment of children suffering from nervous and mental defects. Supporting Dr. Pogue as a supervisory board are Drs. Daniel R. Brower, Sanger Brown, Archibald Church, W. S. Christopher, H. V. Halbert and William G. Stearns. Kindergarten, medical and corrective gymnastics, the correcting of speech defects, articulation, counting of beads and the less exhausting methods of mathematics, modeling in clay, basket and mat weaving and the control and understanding of self are to be taught, each child receiving individual instruction.

GENERAL.

Southern Medical College Association.—There will be a meeting of this association in the Piedmont Hotel, Atlanta, Ga., December 14, at 10 a. m. All southern medical colleges not already members and which desire to affiliate with this association, are requested by the secretary, G. C. Savage, M.D., 139 N. Spruce Street, Nashville, Tenn., to file application at this meeting.

The Warren Triennial Prize (founded by the late Dr. J. Mason Warren in memory of his father) of $500 will be awarded in 1904 for the best dissertation on some subject in physiology, surgery or pathologic anatomy; the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. A high value will be placed on original work. Competing essays must be legibly written. and suitably bound, so as to be easily handled. The name of the writer must be inclosed in a sealed envelope, on which must be written a motto corresponding with one on the accompanying essay. Any clew given by a dissertation or by a writer which reveals his name before the award of the prize will disqualify him. If no essay is considered worthy, no award will be made. April 14, 1904, is the last day on which manuscripts may be received by Dr. Herbert B. Howard, resident physician, Massachusetts General Hospital, Boston.

CANADA.

British Columbia Examination.—Of the 13 candidates before the examiners of the British Columbia Medical Council this month, 11 were successful.

More Montreal Smallpox.—The Montreal Civil Smallpox Hospital, which has been closed for some time, is again open with 10 patients, all of whom it is asserted came from outside places.

In the Montreal General Hospital, in October, there were admitted to the wards 250; discharged, 229; deaths, 12; average daily sick, 190. There were 2,532 consultations in the outdoor departments. Typhoid fever cases have decreased to 24.

Ottawa Medico-Chirurgical Society Formed.—This society is formed by the union of the two medical societies of Ottawa, and the first meeting occurred November 5. Dr. H. Beaumont Small delivered the presidential address on "Medical Memoirs of Bytown," the old name of Ottawa before it became the capital of the dominion. The society will meet on the first and third Thursdays of each month. Sir James Grant, M.D., is the honorary president.

Personal.—Dr. M. O. Klotz, Ottawa, a graduate of Toronto University, will be appointed governor's fellow in pathology at McGill University.——Dr. J. C. Mitchell, ex-president of the Ontario Medical Association, assistant physician at the Toronto Asylum for the Insane, has been appointed by the Ontario government medical superintendent of the new epileptic hospital now being erected at Woodstock, Ont. Dr. Mitchell has been granted four months' leave of absence to visit similar institutions.

St. John Physicians Arrested for Not Reporting Births.—The law in New Brunswick formerly required the parents, a clergyman or the attending physician to report a birth. On the ground that the physician can better serve the cause of vital statistics, the law was amended so as to make this duty devolve on him. One day last week nearly all of the physicians of St. John appeared in the police court, summoned because of neglect to comply with this law. There being no compensation, the physicians have resented the law and seem not to have obeyed it.

British Columbia Medical Society.—The fourth annual meeting took place at Victoria, October 30 and 31, under the presidency of Dr. O. M. Jones, Victoria. Several physicians were present from the state of Washington, and took a lively part in the discussions. The presidential address dealt chiefly with medical education, deplored the money-making tendency of the modern medical college, and advocated raising the ideal of medical teaching and the maintenance of the noblest ethics of the profession. The following were the officers elected: President, Dr. A. P. Proctor, Kamloops; vice-president, Dr. Boyle, Vancouver; secretary, Dr. B. Jack, Vancouver.

Toronto Has Excellent Water.—A series of bacteriologic analyses of Toronto's drinking water have been made for four months. The highest rate reached was on September 30, when 1,120 colonies were registered per cubic centimeter, but these were mostly water forms, no gas-forming bacilli occurring. The lowest register was on October 24, the number reaching 240. Ten years ago the analysis used to show 20,000. It is thought that this record can not be beaten on this continent. Records have been kept weekly in the health department since 1893. The improvement in the water in the last ten years is due to the steel section of the conduit from the lake having replaced the old wooden one, and to the new settling basin.

Toronto Dispensary for Consumptives To Be Established.—The National Sanitarium Association has announced, with especial approval of the medical profession of Toronto, their intention to establish in Toronto a free dispensary for outdoor consumptive patients. In the same building it is proposed to have a lecture hall for students. The Toronto Free Consumption Hospital, now being erected about five miles away, and which will have accommodation for fifty patients, is almost completed. In connection with this hospital there are about forty acres of land, and the expenditure will reach $25.000, but another $25,000 is to be further spent, and toward this purpose a committee of prominent Toronto citizens are collecting funds.

FOREIGN.

Medical Affairs in Holland.—The present government of Holland is strongly in favor of homeopathy and faith healing, and loses no opportunity to discredit the medical profession. The authorities have even gone so far as to invite to the chair of pharmacognosy and pharmacodynamics at the University of Leyden a certain Mende-Ernst of Zurich, formerly a minister, well known throughout Switzerland as a charlatan and homeopath. The call was made at the instance of the prime minister, under protest from the faculty.

Resignation of Eulenburg.—The *Deutsche Med. Wochenschrift* was founded in 1871 by P. Börner at Berlin, and conducted after his death by S. Gutmann, until the latter died in 1893. Since that year this model medical journal has been in charge of Prof. A. Eulenburg, Geh. Med.-Rath, and of Professor J. Schwalbe. We regret to learn that Eulenburg's other duties have compelled him to sever his connection with

the journal. His resignation is to take effect at the close of the year. He has been one of the pioneers in the closer organization of the medical press in his own country and throughout the world.

The Austrian Trouble.—In Austria the government, through its representatives in parliament, seems to have publicly identified itself with the ignorant enemies of science and progress. Our Austrian exchanges comment with grief on this disgrace to their country. The culmination of the trouble was reached in a discussion of vivisection in the lower Austria Landtag. Several members, including the speaker of the house, accused the members of the medical profession, especially certain world-famous Vienna professors, of experimenting on poor patients and of other obnoxious practices in the line of vivisection. The matter was referred to a committee whose report recommends that all the laboratory animals should be removed from the clinics of the gynecologists Chrobak and Schauta. The dean, Professor Weichselbaum, and the other members of the faculty have publicly protested against this measure and the profession throughout Europe is watching aghast this dark cloud that is obscuring the brilliancy of the famous Vienna school. A public meeting of protest has been held at Vienna by the students and professors, and the medical chamber passed a unanimous resolution that the members of the national health service should resign in a body. The minister of education has tried to conciliate the profession, urging them not to take the words of the speaker of the house too seriously and exaggerate their import. Our Berlin exchanges quote Billroth's complaints of the indifference if not actual enmity of the legislators, even as long ago as 1874, and the conditions have evidently not improved since then. It is only a few weeks ago that the Austrian authorities decreed that cancroin should be tried on an extensive scale in certain Vienna hospitals, as mentioned at the time in this column.

Correspondence.

The Red-Light Treatment of Smallpox.

PHILADELPHIA, Nov. 14, 1903.

To the Editor:—I deem it proper to briefly reply to Dr. Finsen's article on "The Red-Light Treatment of Smallpox," which appeared in the last number of THE JOURNAL.

I wish to make public acknowledgment that I have done Dr. Finsen an injustice in stating that the red-light treatment did not originate with him. A treatment, which in effect was a sort of red-light treatment, was certainly employed by John of Gaddesden, but Dr. Finsen calls attention to the fact that the exclusion of the actinic rays of the sun was not its purpose, and that the red blankets and hangings, in all probability, did not exclude all daylight.

As to the value of the so-called red-light treatment, I am more convinced than ever of its inutility as additional clinical evidence comes to hand. I regret very much that Dr. Finsen did not discuss some of the theoretical objections to his theory. It appears to me that one of the strongest arguments against the correctness of Finsen's view is that the negro, whose skin is protected against the entrance of actinic solar rays by a blackish pigment—a far better barrier than red screens—is just as liable to die from smallpox or to be pitted by the disease as his white neighbor. Dr. Finsen has himself stated that "pigmentation constitutes a defense against the effects of the chemical rays." If his statement is true, and if the negro is not protected (which is an irrefutable fact) then the conclusion is imperative that chemical rays of light have nothing to do with pustulation in smallpox.

In support of his red-light treatment, Finsen quotes the results of treatment of 150 cases of smallpox in northern Europe. How often in the history of medicine have wonderful powers been attributed to therapeutic agents because of apparent clinical results. Rectal injections of hydrogen sulphid, the original tuberculin and a host of once loudly-acclaimed measures and drugs have after a time been lost sight of. Dr. Nelson D. Brayton, Indianapolis, has observed many cases of smallpox treated in red-light wards. He writes: "With an experience of at least 300 cases, I regret that I also must corroborate the results that Dr. Welch and Dr. Schamberg arrived at in Philadelphia, in the two cases in which they tried the red-light treatment of the disease, and say there is nothing in it. While it may sound well in theory and look beautiful in practice, it is nevertheless true that the dead are still removed, and the pitted and scarred still recover in a red-light hospital."

In order that the truth may be arrived at, it is important that negative and unfavorable results, as well as the successful ones, should be brought to public attention.

1636 Walnut Street. JAY F. SCHAMBERG, M.D.

Dose of Carbolic Acid and Dosage in General.

NEW YORK, Nov. 14, 1903.

To the Editor:—In reference to the dose of carbolic acid, I should like to say that I personally know a patient who is taking one-half dram, or 30 minims, of pure liquefied carbolic acid at a dose two or three times a day. He has been taking it for some time, and with apparent great benefit. Of course, he has reached the dose gradually, starting with one or two minim doses. I might take this opportunity to add that our so-called science of posology is in an uncertain, chaotic condition, and that no intelligent physician, who is able to watch and interpret effects, should be hampered by book doses. He need not be afraid of being styled a homeopath, if he thinks he gets good effects from and, therefore, prescribes doses much below the accepted minimum; nor, on the other hand, should he hesitate to order doses much above the dispensatory and dose-book maximum if he thinks such doses are demanded by the exigencies of the case. I have more than once prescribed doses which staggered the druggist—such as one ounce of bismuth subnitrate at a single dose, in gastric ulcer, 1/20 gr. of atropin sulphate in suspected intussusception—but which produced the happiest results on the patient. It would be well if the various board examiners gave a little more latitude to the candidates in the subject of posology. WM. J. ROBINSON, M.D.

The County Society and the Index Medicus.

ELKTON, MD., Oct. 30, 1903.

To the Editor:—The Cecil County (Md.) Medical Society has subscribed to the *Index Medicus*. I have thought that if a good proportion of the county societies would become interested in this matter, and follow the example of this Maryland society, the continued existence of this important journal would be assured. We propose to deposit the numbers in a public place accessible to all our members. I take it that making a universal index of medical literature available to the mass of the profession can not fail to have far-reaching results beyond the demonstration of the ability of organization in creating and sustaining great professional enterprises.

CHARLES M. ELLIS, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE HIPPOCRATIC OATH.

WISCONSIN, Nov. 13, 1903.

To the Editor:—Will you kindly give me the form of the oath or obligation that is administered to all graduates in medicine?

D. D.

ANSWER.—Our correspondent probably refers to the Hippocratic Oath, which is as follows:

"I swear by Apollo the physician and Œsculapius and Health, and All-heal and all gods and goddesses, that, according to my ability and judgment, I will keep this Oath, and this stipulation to reckon him who taught me this art equally dear to me as my parents, to share my substance with him, and relieve his necessities if required, to look on his offspring in the same footing as my own brothers and to teach them this art, if they shall wish to learn it, without fee or stipulation, and that by precept, lecture and every other mode of instruction, I will impart a knowledge of the art to my own sons and those of my teachers, and to disciples bound by stipulation and oath, according to the law of medicine, but to none others. I will follow the system of regimen which, according to my ability and judgment, I consider for the benefit of my

patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to anyone if asked, nor suggest any such counsel; and in like manner I will not give to a woman a pessary to produce abortion. With purity and with holiness I will pass my life and practice my art. I will not cut persons laboring under the stone, but will leave this to be done by men who are practitioners of this work. Into whatever houses I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption; and further from the seduction of females or males, of freemen and slaves. Whatever in connection with my professional practice or not in connection with it, I see or hear, in the life of men, which ought not to be spoken of abroad, I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this Oath unviolated, may it be granted to me to enjoy life and the practice of the art respected by all men in all times. But should I trespass and violate this Oath, may the reverse be my lot."

A modified form of this oath was administered this year to graduates in medicine of the Syracuse University; this was published in THE JOURNAL, July 4, 1903. It is not usual to administer any oath in the majority of medical colleges. The graduates are supposed to be instructed as to their ethical obligations and expected to fulfill them.

TREATMENT OF GONORRHEAL ANKYLOSIS OF KNEE.

WEATHERFORD, TEXAS, November, 1903.

To the Editor:—What is your advice in a case of ankylosis of knee from gonorrheal arthritis? (Jan. 11, 1903.) The patient is a young man, aged 23, general health good; he has been up six months, has been at work some two months, has had every means of treatment except surgical, including 30 treatments by dry hot air. The knee is flexed 5 9/16 inches while the patient is lying on a horizontal plane. It is impossible to get any movement in the knee. It swells a little during the day's use.

DR. ROBERT R. NORWOOD.

ANSWER.—If under anesthesia the ankylosis of the knee is found to be bony, nothing can be done, unless the angle of deformity is so great as to warrant an open operation in order to correct this, in which case, of course, the knee would be stiff in its new position. If the adhesions are not bony, but can be broken up under an anesthetic, this should be done. The knee should then be bandaged—not too tightly—with a rubber bandage and enclosed in hot fomentations to relieve the pain and prevent too much swelling. Thereafter the joint should be moved at least once a day, in order that the adhesions may not reform, and the dressing should then be reapplied. This will be very painful, and will require a great deal of perseverance on the part of the surgeon, and of endurance and grit on the part of the patient, to thoroughly carry it out. It will also require several months' treatment.

Marriages.

MYRON L. HUNTINGTON, M.D. to Mrs. Jennie Garrett, both of Moline, Ill., November 5.

M. BOWMAN HOOD, M.D., to Miss Mabel Glyndon Joyner, both of Baltimore, November 4.

JOHN A. BAUER, M.D., to Miss Elizabeth Schlarmann, both of Germantown, Ill., October 28.

RICHARD L. NEER, M.D., Baltimore, to Miss Effie Maude Bennett, at Portland, Ore., November 3.

EMMETT J. CRAIG, M.D., U. S. Army, to Miss Annie Laurie Miller of San Diego, Cal., November 1.

LEONARD C. CHAMBERLAIN, M.D., to Miss Jeannette G. Drysdale, both of New Orleans, La., November 11.

FRANCIS S. FURMAN, M.D., Shreveport, La., to Miss Sarah Chandler, at Johnson City, Tenn., November 4.

VOLNEY McR. SHOWALTER, M.D., Point Clear, Ala., to Miss Charlotte McGraw, at Bradford, Pa., November 3.

FRANK TORNHOLM, M.D., Wahoo, Neb., to Miss Anna Josephine Pierson of South Bend, Ind., October 28.

AUGUST E. KROENING, M.D., Lincoln, Ill., to Miss Nellie Bellmar of Springfield, at Wilmington, Ill., October 28.

Deaths.

GEORGE JULIUS ENGELMANN, M.D.

George Julius Engelmann, M.D., Boston, died suddenly in Nashua, N. H., November 16, aged 56. While on a brief vacation he caught cold, pneumonia developed rapidly and all treatment was unavailing. He leaves a wife and three children. The burial took place yesterday in St. Louis.

Dr. Engelmann was born in St. Louis, July 2, 1847, and received his early education at Washington University, from which he graduated with the degree of master of arts in 1869. He took a medical course at the universities of Tuebingen, Berlin, where he obtained his medical degree in 1871, and in Vienna, where he obtained a degree of master of obstetrics a year later. He served as surgeon in the Franco-Prussian War and returned to St. Louis in 1873, where he practiced until 1895. His practice was devoted almost exclusively to gynecology and obstetrics. In 1895 he moved to Boston. He was an extensive traveler, and as a recreation made researches in the lines of ethnology and archeology. His collection of Missouri flints and pottery, which is now in the Peabody Archeological Museum in Cambridge, Mass., is justly renowned. He was a member of the American Medical Association, president of the American Gynecological Society in 1894-5, honorary president in 1884, and president in 1900 of the Gynecological Section of the International Medical Congress, honorary president of the International Congress of Obstetrics and Gynecology in Brussels, 1892, and in Amsterdam, 1899. He was president of the Boston Obstetrical Society, and a fellow of the British Gynecological and London Obstetrical societies.

He was professor of the diseases of women in the Missouri Medical College, St. Louis, and in the Post-Graduate School

GEORGE JULIUS ENGELMANN, M.D.

of Medicine in that city. He was a strong and forceful writer and chief among his contributions to literature are his works on "Mucous Membrane of the Uterus," published in 1875, on "Labor Among Primitive Peoples," 1882, which passed through two editions in English and was translated into French and German, and monographs in the line of his specialties.

Lucius Gillette Thompson, M.D. Starling Medical College, Columbus, Ohio, 1849, one of the founders of the Illinois State Medical Society, and first vice-president of the North Central Illinois Medical Association, died at his home in Lacon, Ill., October 30. In company with the late Dr. Robert Boal he drove from Lacon to Springfield in June, 1850, in response to a call for a state medical convention issued by the Ottawa Medico-Chirurgical Association. At this meeting 16 physicians were present, and the state society was organized. At its semi-centennial in 1900 Drs. Boal and Thompson were the sole survivors of those who organized the society.

Henry A. Clarke, M.D. Rush Medical College, Chicago, 1875, died suddenly at his home in Pueblo, Colo., October 18. At a meeting of the Pueblo County Medical Society, October 20, resolutions testifying to the worth of Dr. Clarke were adopted.

August C. Sapper, M.D. Missouri Medical College, St. Louis, 1893, chief of the medical staff of the Lutheran Hospital, St. Louis, died in that institution, November 8, from malignant disease, after an illness of five months, aged 35.

J. McFadden Gaston, M.D.—As we go to press we learn that Dr. J. McFadden Gaston, the noted surgeon of Atlanta, Ga., died at his home November 15, aged 79. An extended notice will appear in the next issue of THE JOURNAL.

William Wallace Seely, M.D. Medical College of Ohio, Cincinnati, 1864, professor of clinical ophthalmology and otology in the Medical College of Ohio, died at his home in Cincinnati, November 8, after a long illness, aged 66.

Emil Rosenberg, M.D. University of Berlin, Germany, 1855, senior medical examiner of the Northwestern Mutual Life Insurance Company, died at his home in New York City, November 4, aged 74.

Noah D. Jenkins, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1886, died at his home in Mark, Iowa, November 5, from the effects of the excessive use of liquor and drugs, aged 55.

E. C. Walters, M.D. Jefferson Medical College, Philadelphia, was found dead in his office in Washington, Pa., November 5, aged 35. Death is supposed to have been due to alcoholism.

Franklin von Artsdalen, M.D. Jefferson Medical College, Philadelphia, 1857, died at his home in Philadelphia, November 15, from kidney disease of long standing, aged 69.

Benjamin A. Andreas, M.D. Jefferson Medical College, Philadelphia, 1888, died suddenly at his home in South Bethlehem, Pa., October 26, from heart disease, aged 43.

Augustus Remick, M.D. Harvard University Medical School, Boston, 1868, a member of the American Medical Association, died in Providence, R. I., October 5, aged 64.

John Craig Nevins, M.D. Jefferson Medical College, Philadelphia, 1874, died at his home in Summit Hill, Pa., October 26, after an illness of nine months, aged 64.

Benjamin F. Sheeder, M.D. Jefferson Medical College, Philadelphia, 1893, died recently at his home in Saline, Mich., after an illness of two years from paralysis.

Nathaniel Jewett, M.D. Eclectic Medical College of the City of New York, 1871, died at his home in Ashburnham, Mass., November 3, after a long illness.

Morgan Clements, M.D. Jefferson Medical College, Philadelphia, 1848, died at his home near Tuscaloosa, Ala., November 1, after a short illness, aged 78.

James R. Sims, M.D. Eclectic Medical Institute, Cincinnati, 1883, Memphis Hospital Medical College, 1889, of Du Quoin, Ill., died October 11.

William R. Jenkins, M.D., of Freeman, Mo., died at the University Hospital, Kansas City, Mo., October 28, from cystitis, aged 48.

Samuel Henry Warren, M.D. University of Buffalo, 1880, of Buffalo, died from alcoholism at Riverside Hospital, Buffalo, October 29.

Louisa May Shryock, M.D. University of Wooster, Cleveland, 1893, of Butler, Pa., died at North Washington, Pa., November 3, aged 36.

David A. Pease, M.D. Cincinnati Medical College, died at his home in Twin Bridges, Mont., November 3, from heart disease, aged 72.

William H. H. Jackson, M.D. Cleveland Medical College, 1868, died suddenly at his home in Oil City, Pa., October 31, aged 63.

John Herbert Trout, M.D., Canada, of Toronto, Ont., died at Dubuque, Iowa, November 1, after a long illness, aged 29.

George Tallmadge Brown, M.D. New York University, 1879, died at his home in Margarettsville, N. Y., October 30.

Horace E. Jones, M.D. Barnes Medical College, St. Louis, 1899, of Thompsonville, Ill., died October 16.

Frank Judson, M.D., 1891, died at Dixon, Ill., October 28, after a surgical operation, aged 36.

Marcus L. Schlesinger, M.D. University of Moscow, Russia, 1889, of Chicago, died October 7.

Herman Rakenius, M.D. Rush Medical College, Chicago, 1878, of Chicago, died recently.

Adelia Barlow Diven, M.D., 1877, died at her home in Chicago, November 7, aged 59.

Franklin Hollen, M.D., 1878, of Clay County, Ill., died October 14.

Bennett F. Hopkins, M.D., 1893, of Rapatee, Ill., died recently.

Marcus L. Brown, M.D., 1877, of Enfield, Ill., died October 13.

James C. Scott, M.D., 1887, of Waynesville, Ill., died recently.

Edward R. Roe, M.D., 1881, of Chicago, died in October.

A. M. Ross, M.D., 1892, of Argenta, Ill., died recently.

Miscellany.

Improvement in Vital Statistics.—Effective co-operation has been instituted between the American Medical Association, the American Public Health Association, the Conference of State Boards of Health, the United States Census Bureau and the United States Public Health and Marine-Hospital Service for the improvement of the vital statistics of this country. Among the objects sought are the extension of adequate methods of registration, the use of uniform and comparable tables and rates in bulletins and reports and the improvement of the international classification of causes of death. A pamphlet on "Statistical Treatment of Causes of Death" has been issued by the United States Census Bureau, requests for which should be addressed to Mr. W. A. King, chief statistician for vital statistics, Census Bureau. It has special reference to the difficulties encountered in compiling deaths returned from several causes, and asks for the co-operation of the profession in framing a thoroughly satisfactory method of procedure in such cases.

Improved Local Antitoxin Treatment of Tetanus.—J. A. Sicard of Paris was the first to administer tetanus antitoxin by the lumbar subarachnoid route, and besides the 20 cases published by Vallas last year he knows of 6 cases thus successfully treated (2 personally observed), with another which terminated fatally. Experimental research has also established the possibility of curing even severe tetanus by subarachnoid injection of the antitoxin. Two dogs were saved in this way, while by the other routes none were saved in severe infection. Marie and Morax have recently announced that tetanus toxin besides being carried to the brain by the blood, may reach it by way of the peripheral nerves. The impregnation must occur by way of the cylinder-axis, as the cerebrospinal fluid does not become toxic even after subcutaneous injection of large amounts of the toxin. The cylinder-axis conveys the toxin just as it conveys in the opposite direction the trophic current. It is thus able to convey a toxin, a soluble ferment, but not microbian elements. The fact that the tetanus symptoms commence with trismus in man and in the injured limb in inoculated animals is proof of the correctness of this assumption. The peripheral nerves absorb the tetanus toxin from the lymph spaces around and transmit it to the brain as a plant takes up the water from the soil. Sicard applied these new data to the treatment of the disease in his 2 last cases mentioned above, supplementing the subarachnoid injection of the antitoxin by injections, not only at the point of the injury but along the nerve trunks—an amplified form of local treatment. By these *injections para-nerveuses périphériques*, as he calls them, he follows the toxin along its route. Both his patients thus treated promptly recovered. He advises 5 to 10 c.c. of the antitoxin injected around the wound; then 15 to 20 c.c. injected along the peripheral nerves, both the large and the medium, especially in the wounded limb, and the same amount injected into the subarachnoid space. Forty-eight hours later the injections may be repeated with the same doses, and again if needed, but the subarachnoid injections should not be repeated more than once.

A Roman Catholic's View of the Medical Profession.—In the *Ecclesiastical Review* for September is a chapter from the serial "In Father Martin's Library," from which we quote the following conversation: "'The ethics taught in our medical schools are in some respects admirable, and, perhaps, superior to those of any other learned profession. They inculcate a delicate regard for personal feelings, a vigorous exclusion of purely mercenary methods, the duty of safeguarding the interests of a patient, the keeping of secrets, and the maintenance of a recognized professional etiquette, not only toward brother physicians, but toward the ministers of religion. In-

deed, I have often thought that the readiness with which the average physician holds himself bound to answer a call to duty at the sick-bed or in emergency cases, even when it demands of him personal sacrifice out of all proportion to the remuneration held out, might serve us priests as a model when we are called by our poor people to administer to them the comforts of religion, which they covet even more than bodily relief or health.' 'I should suppose that a physician's reputation, and consequently his practice, depend on such conduct,' I said tentatively. 'Assuredly. But there are other motives that operate in most cases, and which indicate a naturally more sensitive or compassionate—I should say, perhaps, religious—disposition of mind. In the first place, the very attraction that leads a man to take up the profession of medicine betokens ordinarily a sympathetic nature. It is true that the methods of the dissecting room tend to brutalize a disposition naturally coarse or reckless; but for this the actual suffering which subsequent experience reveals to the practitioner in a thousand different forms of light and shade, furnish a strong antidote. No man, unless it be the priest who has to administer to a large community of needy souls, sees so much of the inner workings of human life, the true and false, as does the physician; and, if his mind be open, it can not but arouse in him motives which tend toward the real, the permanent, as opposed to the unrealities of our temporary existence. And this I hold to be the preamble to religion, as much as reflection is a condition of all spiritual consciousness and activity, etc., etc.!'"

Book Notices.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. VIII. Materia Medica and Therapeutics, Preventive Medicine, Climatology, Suggestive Therapeutics, Forensic Medicine. Edited by George F. Butler, Ph.G., M.D.; Henry B. Favill, A.B., M.D.; Norman Bridge, A.M., M.D.; Daniel R. Brower, M.D., and Harold N. Moyer, M.D. July, 1903. Vol. IX. Physiology, Pathology, Bacteriology, Anatomy, Dictionary. Edited by W. A. Evans, M.S., M.D.; Adolph Gehrmann, M.D., and William Healy, A.B., M.D. August, 1903. Vol. X. Skin and Venereal Diseases, Nervous and Mental Diseases. Edited by W. L. Baum, M.D., and Hugh T. Patrick, M.D. September, 1903. Cloth. Pp. 326, 233 and 236 Respectively. Price, $1.50 and $1.25 Respectively. Chicago: The Year-Book Publishers.

In the July number of this series we have "Materia Medica and Therapeutics" by Dr. George F. Butler, who reviews the literature very thoroughly. A useful portion of the work is a list of the new proprietary remedies taken from *Merck's Archives*. "Preventive Medicine" is ably treated by Dr. Favill, and "Climatology, Suggestive Therapeutics and Forensic Medicine" by such well-known writers as Drs. Norman Bridge, Brower and Moyer. In the August issue we have the subjects of "Pathology" by Dr. W. A. Evans and "Physiology, Bacteriology and Hygiene" by Dr. Gehrmann. In conclusion a supplement to the medical dictionaries, containing the new medical terms, is furnished by Dr. William Healy. The usefulness of this last addition is apparent. In the September number Dr. W. L. Baum reviews the literature of skin and venereal diseases. This part of the work is well illustrated. Nervous diseases are treated of by Dr. H. T. Patrick, assisted by Dr. Charles L. Mix, who give the gist of what is new in this subject within the past year. The contribution to the subject of mental diseases is rather brief. This portion of the work does not fully represent all the valuable literature that has appeared on this subject within the period covered. As a whole the volumes fully bear out the reputation of the preceding ones. The series is a most valuable one and unique in its convenience and inexpensiveness.

THE MEDICAL ANNALS OF MARYLAND. 1799-1899. Prepared for the Centennial of the Medical and Chirurgical Faculty. By Eugene F. Cordell, M.D., Baltimore. 1903. Cloth. Pp. 888. Baltimore: Williams & Wilkins Co. 1903.

There are few commonwealths that have had the opportunity to have their medical history so well compiled as Dr. Cordell has done in this work for Maryland. It gives a valuable résumé of the principal facts as regards medical practice and medical history in the state during the nineteenth century. It is divided into three sections, the historical, the biographical and the chronological. The first gives the annals of the medico-chirurgical faculty—the state society—during its century of existence, with some notices of earlier organizations in the state. The second gives a brief biographic note of each member of the society so far as the records show from the beginning, making a total of about 2,400 persons. In the last section there is an account of the principal medical facts occurring in each year, and especially biographical notices of leading members of the profession in the state. The numerous portraits which embellish the text are a very valuable addition to the work and have evidently been carefully collected from the best available sources. It is something to know how our predecessors looked and the longer the time that has elapsed the more interest we have in them. The book is elegantly printed on excellent paper, its text is admirable and the industry and good judgment of the compiler are worthy of all praise.

ANALYSIS OF THE SEXUAL IMPULSE—LOVE AND PAIN—THE SEXUAL IMPULSE IN WOMEN. Third Volume in Series, "Studies in the Psychology of Sex." By Havelock Ellis, L.S.A. (England); Fellow of the Medicolegal Society of New York and Anthropological Society of Berlin. Cloth. Pp. 266. Price, $2.00 net. Philadelphia: F. A. Davis Company.

This is another volume in the series discussing sexual matters and is perhaps the most valuable one that has yet appeared. It treats of the fundamental principles and gives especial attention to an analysis of the sexual impulse in women. The many diseases and conditions in which the influence of sexual desire and gratification is sometimes discovered after having been ignored suggest the value of this book to the physician, especially to the neurologist. With his enthusiasm in and familiarity with the subject, Ellis goes into details that seem unnecessary and unpleasant—a criticism that would not be needed if the work were only placed in the hands of specialists.

THE NEUROLOGICAL PRACTICE OF MEDICINE. A Cursory Course of Selected Lectures in Neurology, Neuriatry, Psychology and Psychiatry. Applicable to General and Special Practice. With 177 Illustrations. After the Author's Class-Room Methods as a Teacher of Students. Designed for Students and General Practitioners of Medicine and Surgery. By Charles H. Hughes, M.D., President of the Faculty and Professor of Neurology, Psychiatry and Electrotherapy, Barnes Medical College. Cloth. Pp. 417. Price, $3.00. St. Louis: Hughes & Co.

Dr. Hughes has published in this volume the first series of his lectures on neurology given in the Barnes Medical College. The book contains a useful demonstration of the neuron theory, the methods of examination in nervous diseases and the general anatomy of the nervous centers, touching also on some pathologic points. The lecture style is clear and the subject-matter is given in an interesting as well as an instructive manner. The work is amply illustrated, not overloaded with technical matter and for that reason is so much better for the student, while at the same time it successfully conveys the instruction that it is intended to give.

PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST. By Richard C. Cabot, M.D., Physician to the Out-patients, Massachusetts General Hospital. Second Revised Edition. With 147 Illustrations. Cloth. Pp. 319. Price, $2.50 net. New York: Wm. Wood & Co. 1903.

Cabot's excellent work on diagnosis of diseases of the chest has won for itself a favorable place, and this edition will be welcome. For a convenient short manual on the subject we do not known of any work that is its superior. The present issue is beautifully gotten up and amply illustrated.

Association News.

AMERICAN MEDICAL ASSOCIATION.

Proceedings in the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-fourth Annual Session at New Orleans.

Dosage of Liquid Medicines.

The following is the report of the Committee on Dosage of Liquid Medicines and the action taken thereon, as reported in THE JOURNAL, May 23, 1903, page 1455:

To the Section on Materia Medica, Pharmacy and Therapeutics of the American Medical Association:

Your committee, appointed at the last session of this Section to consider the recommendations contained in the paper entitled "Dosage of Liquid Medicines: a Simple Plan for Greater Accuracy and Metric Measurements," communicated by Carl S. N. Hallberg, Chicago, respectfully reports as follows:

That, after giving the subject due consideration, they find that Professor Hallberg's criticism on the common methods of designating dosage of liquid medicines is well founded and just, and that the remedy he suggests to overcome the present indefiniteness and uncertainty, namely, the adoption of a standard pipette for dropping doses, and standard metric equivalents for the teaspoon and tablespoon, will be likely to overcome these evils to a great degree, and will favor uniformity and accuracy in the administration of this class of pharmaceutic preparations.

That we recognize the fact that the metric equivalent of the modern teaspoon averages five cubic centimeters, and the tablespoon fifteen cubic centimeters, and would suggest that this fact shall be borne in mind by physicians in ordering doses of liquid medicines. The Philadelphia College of Pharmacy last year adopted the following resolution: "The use of properly made and accurately graduated glass dose measures is to be commended. These measures, however, are to be so constructed that the height of the contained liquid at a spoonful mark is greater than its diameter." Approving this recommendation, the committee has devised a graduated measure for domestic use, which it believes has especial advantages over the usual form of measuring glass. Externally, it is cylindrical; internally, it is cylindrical down to the 15 c.c. mark, and below this point it is an inverted cone. A slight projection or ridge on the inner surface indicates the level for 5 c.c., and another at the base of the inverted cone indicates the lever for the 15 c.c. measure. The total capacity is 30 c.c. This is believed to be a convenient size and sufficiently large for the ordinary administration of liquid medicines, corresponding with one teaspoonful, one and two tablespoonfuls.

The committee also recommends the adoption of a standard medicine dropper or pipette, of 3 millimeters external diameter, which will deliver twenty drops of water, at 15 degrees C., which will measure 1 cubic centimeter when dropped at the rate of one per second, for the administration of doses less than the teaspoonful.

Your committee does not approve the suggestion to alter the values of some of the denominations of customary weights and measures, believing that such action might tend to confuse the subject rather than to facilitate the introduction of the metric method, which is the end desired.

[The report concluded with resolutions which were recommended for adoption by the Section. They are given below as finally adopted.]

FRANK WOODBURY,
AUGUSTUS A. ESHNER,
HORATIO C. WOOD, JR.,
Committee.

On motion the resolutions were adopted as follows:

To the House of Delegates: The following resolutions have been adopted by the Section on Materia Medica, Pharmacy and Therapeutics, and the delegate from that Section instructed to present them to the House of Delegates, with the recommendation that they be adopted by the Association:

Resolved, That teachers of medicine and pharmacy, editors of medical and pharmaceutic journals and authors of text-books are respectfully requested to give precedence to the metric method in the writing of all medical formulas and that, for the administration of doses of less than a teaspoonful, the quantity be stated in drops delivered from a standard medicine dropper or pipette of three millimeters external diameter, which will deliver twenty drops of water at 15 C., which will measure one cubic centimeter when dropped at the rate of one per second, and that the teaspoonful be considered as equivalent to five cubic centimeters and that the tablespoonful be considered as equivalent to fifteen centimeters; and

Resolved, That the orthography, abbreviation, etc., of the International Bureau, or as revised by the National Bureau of Standards at Washington, shall also be recommended for adoption in medical and pharmaceutic publications: and

Resolved, That a copy of these resolutions be transmitted to the Committee of Revision of the United States Pharmacopeia for 1900, with the request that they be incorporated, as far as possible, in the United States Pharmacopeia.

Nerve Nostrums and Drug Addictions.

The following is the report of the Committee on Nerve Nostrums and Drug Addictions and the action taken thereon, as reported in THE JOURNAL, May 23, 1903, page 1455:

The use of proprietary medicines, and especially the so-called nerve tonics and nerve sedatives, has rapidly increased in the past few years, and there seems no likelihood of their decrease unless some systematic plan is made to check this rapidly growing evil. The medical profession owes it to itself and to humanity to take a decided stand on the subject. While we are unable to get rid of the charlatan and faker, while we have motes in our own eyes, it devolves on us as teachers of hygiene to so educate the public that the nostrum business will be reduced to a minimum.

While the profession as a whole is opposed to nostrums, no organized plan to expose their fraudulent claims has yet been made. A few good papers have appeared sporadically in certain medical journals. Evidently the profession has thought that fads and fakers would die out if left alone with "their rope," but such is not the case.

The advertising media of proprietary medicines are: The physician's use of them, the religious press, the lay press, and their own printing presses. Nine of the most widely-read influential religious papers published by the Methodists began the new year by dropping the patent medicine ads. Even the lay press has begun to feel the hand of progress and civilization. Several of the leading newspapers in the east, in Philadelphia, New York and Boston, do not print objectionable medical advertisements.

Dr. Spratling has well said that the quack's secrecy is his only stock in trade; dispel the mystery surrounding him and he will disappear like mist before the rising sun. The term "patent" applied to these medicines is a fraud, pure and simple, because if they were patented their composition would be known and the "valuable discovery" would be free to the public when the patent ran out, as in the case of Castoria. Instead, they are kept secret, and are given protection and a perpetual monopoly on their names through the copyright and trade-mark laws. Some modification of these laws is a necessity.

LEGISLATION BY CONGRESS.

The opportunity is now with us to go before Congress and ask that body to regulate the interstate commerce in proprietary medicines. Such a law would be easier to pass than to break through the state legislature, which is controlled by country newspapers, whose very existence generally depends on the money paid for the advertisements, many of which are unfit to be read in any home in any civilized land. Such a measure should require that the formulas of all proprietary medicines be registered with some department of the Federal government, for instance, the recently established drug laboratory at Washington, and that the sale of all medicines containing any dangerous substances or habit-forming drugs be prohibited unless an exact and correct formula of the ingredients and their quantities be attached to the bottle.

DRUG ADDICTIONS.

With reference to the uses of hypnotics and analgesics and resultant drug addictions, we would recommend that the patient should never be advised of the character of the medicinal agent employed, that every precaution should be taken against such information as may lead to self-medication and its sequelæ of drug habits.

The addiction to drugs that enslave is too often caused by carelessness on the part of the physician giving verbal directions to the patient to take "so and so," or by informing him that he will give him something which will quickly afford relief from some acute pain, etc. The custom of prescribing some of these preparations in the original package, thus familiarizing patrons with the name and properties of

these medicines, is also a dangerous practice, leading to self-medication, and should not be countenanced by reputable physicians. Many of these preparations "prepared solely for physicians' use," are now sold as regular "patent medicines," even at cut rates in department stores. And let it be said to the shame of the medical profession that nearly a score of such medicines are advertised in medical journals, thus giving them a quasi endorsement.

LACK OF SCIENTIFIC NOMENCLATURE.

More general information concerning the Pharmacopeia and its unofficial supplement, the National Formulary, would lessen the necessity of resorting to unofficial preparations. The multiplication of these articles, with their often arbitrarily selected copyright titles, confuses the physician and is the bane of the pharmacist's existence. Sometimes the names of entirely different preparations are so similar as to invite error and serious consequences as a result. Even the true synthetic chemicals are open to this serious objection, while the many mixtures masquerading as definite chemical compounds under suggestive therapeutic terms simply make confusion worse confounded. Owing to their being protected often by patent on the product itself, as well as by patent on the process, in addition to a copyright on the trade name, their status is so questionable as to prevent their admission to the U. S. Pharmacopeia, and the medical and pharmaceutical professions are without adequate knowledge as to their identity, purity and strength. Valuable additions to the materia medica are thus submerged by the irresistible flood of nostrums until the physician is at sea and the pharmacist in despair.

Many schemes for segregation have been proposed, the plan pursued in France having received the most favor, as noticed at various times in the journals. There being here no official body corresponding to the French Academy of Medicine, it has been suggested that such committee might be formed from the American Medical Association and the American Pharmaceutical Association.

THE NATIONAL BUREAU OF MEDICINES AND FOODS.

There is about to be organized the National Bureau of Medicines and Foods, the object of which is to undertake work of this character. The bureau proposes to examine medicinal articles and foods, and certify to such as conform to the standard professed by the manufacturer and to be required by the bureau, for the information of the medical and pharmaceutical professions.

In conclusion your committee recommends:

1. That newspapers which do not print objectionable medical advertisements are entitled to and should receive the favor and preference of medical men.

2. That articles on the dangers arising from the use of quack nostrums should be written for such newspapers for publication.

3. That the Committee on National Legislation be asked to consider the feasibility of the introduction in the next House of Representatives an interstate measure prohibiting or limiting the sale of poisonous and dangerous patent medicines.

4. That no medicinal preparation for internal use, as distinguished from antiseptics, disinfectants, cosmetics and dietetics, advertised as a remedy or cure to the laity, is entitled to the patronage of physicians, nor should such be admitted to the pages of the medical journals, nor to the exhibitions of the American Medical Association.

5. That manufacturers be requested to print the scientific or chemical names under the trade names of all pharmaceutical or chemical preparations.

6. That the general plan and object of the National Bureau of Medicines and Foods are entitled to a further careful investigation by a special committee of the American Medical Association.

WM. J. ROBINSON, New York.
A. W. BAER, Chicago.
H. C. WOOD, JR., Philadelphia.

On motion these recommendations were adopted.

State Boards of Registration.

COMING EXAMINATIONS.

Board of Medical Examiners of the State of California, City Hall, San Francisco, Dec. 1. Secretary, Geo. G. Gere, M.D., 825 Market St., San Francisco.

New Mexico Board of Health, Santa Fe, Dec. 7. Secretary, Dr. D. B. Black, Las Vegas.

Examining Board of Medical Society of Delaware, Dover, Dec. 8. Secretary, Dr. P. W. Tomlinson, Wilmington.

Board of the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, Dec. 8.

Ohio State Board of Medical Registration and Examination, Columbus, Dec. 8, 9 and 10. Secretary, Dr. Frank Windeis, Columbus.

Missouri State Board of Health, Southern Hotel, St. Louis, Dec. 14, 15 and 16. Secretary, Dr. W. F. Morrow, Kansas City.

Medical Council, Philadelphia, Dec. 15. Secretary, Dr. Isaac B. Brown, Harrisburg.

Medical Examining Board of Virginia, Lynchburg, Dec. 15-18. Secretary, Dr. R. S. Martin, Stuart.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Dec. 22, 23 and 24. Secretary, Dr. S. D. Van Meter, Denver.

The Confederation of Reciprocating Licensing Boards.—Dr. B. D. Harison, secretary of the American Confederation of Reciprocating Examining and Licensing Medical Boards, calls our attention to some errors and omissions in the report of the meeting of this confederation at St. Louis, October 27, which appeared in THE JOURNAL, November 7, page 1156. He says that four states were represented which we did not mention, namely: Ohio, Pennsylvania, Nebraska and Oklahoma. In our report we mentioned the obstacles to reciprocity. Dr. Harrison states that obstacles in the way of practical reciprocity were not discussed at the meeting except by inference; that it was declared by those states reciprocating under qualifications 1 and 2 that experience in exchanging certificates under these qualifications demonstrated the fact that there were no such obstacles as stated in THE JOURNAL report. "After several months' experience in exchanging certificates," Dr. Harison says, "under both qualifications 1 and 2 the obstacles reported in THE JOURNAL'S report have been demonstrated beyond any question or doubt to have no material existence." Dr. Harison says concerning the discussion on qualification 2 that the change made had no reference to the diploma, but added the requirements of a year's reputable practice in the state subsequent to the receiving of a license before endorsement could be had for a reciprocal license in another state. Qualification 2 as amended reads as follows:

That a certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for reciprocal registration in any other state, provided the holder of such state certificate had been engaged in reputable practice in such state at least one year, and also provided that the holder thereof was at the time of such registration the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date of such diploma was prior to the legal requirement of the examination test in such state.

Dr. Harison further says that the St. Louis meeting was without question the most successful and fruitful reciprocating conference ever held in the United States and that the confederation gained an actual increase of membership of over 66 per cent. and that a greater increase is more than probable within a brief period.

California Report.—Dr. George G. Gere, secretary of the Board of Medical Examiners of the State of California, reports in detail the written examinations held at San Francisco and Los Angeles, July 7 to 9 and August 4 to 6, 1903. The percentage required was 75, there were 9 subjects, 90 questions, and 158 candidates; of the latter, 108 passed and 50 failed, including 14 who were conditioned because of deficiency in certain branches, and who will be required only to take re-

* Graduate 1889. † Graduate 1884. ‡ See dates of graduation below.

examination in those particular branches. By including in the summary those who were conditioned with those who failed, the average failing grades are raised, for example, some were conditioned in spite of average grades of 85 and 80. The year of graduation is recent (1900 to 1903), unless otherwise specified; we call attention to the many graduates of the years 1864 to 1890.

GRADES IN DETAIL.

Cooper Medical College—Passed: 91.3, 86.6 (2), 85.7, 85.1 (2), 84.2, 84.1, 84, 83.4, 83.2, 82.8, 82.5, 81.8, 81.7 (2), 80 8, 80.7, 80.3, 80.1, 79.7, 79, 77.7, 77.2, 76.4, 75.1, 75. Failed: 80.4.79.5, 79.3, 77.6, 72.2. (Those marked 75 or above were conditioned; those below failed entirely.)

University of Southern California—Passed: 89.1, 88.6, 84 6, 84.5, 84.3, 83.4, 83, 82.6, 81.7, 80.4, 79.8 (2), 79.7, 79.6 (2), 79.5, 79.2, 78.1, 75.1.

College of Physicians and Surgeons, California—Passed: 89.2, 87.4, 84.7, 84.4, 84.2, 83.3, 82.7, 81.7, 78.4 (2), 75.5, 75.4, 75. Failed: 85.1, 79.4, 76.6, 74.1 (2), 73.2, 70 3.

University of California—Passed: 87.8, 86.4, 84.7, 84 4, 83.5, 83.1, 81.3, 80, 79, 78.2, 78.1, 77.7, 77.6. Failed: 76.5, 72.4.

Rush Medical College—Passed: 84.5, 83.1 (graduate 1893), 79.1 (1869). Failed: 73.8, 71.5 (1881), 63.5.

Northwestern University—Passed: 87.3, 84.3. Failed: 60.8 (1869).

College of Physicians and Surgeons, Chicago—Passed: 75.3, 75 (1890). Failed: 73.4, 72.7.

Hahnemann Medical College, Chicago—Passed: 83.5, 80.7. Failed: 76.7, 73.5 (1891).

University of Michigan—Passed: 80.5 (1868). Failed. 71.7 (1890), 69.3 (1864), 61.1 (1882).

University of Louisville—Failed: 77.4 (1875), 72.8 (1892), 53.3 (1887).

Bowdoin Medical College—Passed: 75 (1893). Failed: 77.1 (1892), 71.6.

University of Pennsylvania—Passed: 85.5, 75.3 (1891). Failed: 74.1 (1884).

Colleges having but one representative were as follows:

PASSED.

College.	Year Grad.	Grade.
University of Berlin, Germany	1901	76.3
Pulte Medical College, Ohio	1903	75.1
Yale University	1898	81.5
University of Minnesota	1902	80.7
Western Reserve University, Ohio	1900	83.6
Baltimore Medical School	1902	82.8
Harvard University	1901	87.1
Medical College of South Carolina	1884	80.3
University of Colorado	1897	79.8
Washington University, St. Louis	1900	79.6
Jefferson Medical College, Philadelphia	1875	75.2
Kentucky School of Medicine	1885	79.7
University of Buffalo	1899	80.7
Barnes Medical College, St. Louis	1897	80.7
University of Niagara	1898	77.8
Creighton Medical College, Omaha	1900	78.5
University of Georgetown, D. C.	1902	77.2

FAILED.

Vanderbilt University, Tennessee	1903	76.3
New York University Medical College	1896	66.1
New York Homeopathic Medical College	1903	76.4
Apothecaries' Hall, Ireland	1899	75.3
University of Basle, Switzerland	1902	73.1
Tufts Medical College, Boston	1901	71.2
Laval University, Montreal	1901	69.6
University of Vienna, Austria	1891	74.0
Detroit Medical College	1897	61.6
Chicago Homeopathic Medical College	1879	65.2
Hahnemann Medical College, California	1901	71.3
University of the City of New York	1886	71.7
University of Iowa	1883	70.5
McGill University	1875	73.1

The questions asked were as follows:

MATERIA MEDICA (AUGUST).

1. What is meant by rational therapeutics? Empirical therapeutics? 2. Name three drugs that increase the amount of urine by raising the general blood pressure. Three that increase the quantity by acting locally on the kidney. 3. Name five drugs that are liable to cause an eruption on the skin when given in large doses. 4. Give five drugs that are supposed to have an antiseptic action on the intestinal tract. 5. Name a drug that has a physiologic action practically antagonistic to each of the following: Aconite, chloral-hydrate, morphin. 6. Name a drug that has a physiologic action practically synergetic with the above. 7. What is the composition of Blaud's pills? 8. Write a prescription for chronic constipation such as is commonly met with in patients of sedentary habits. 9. Name and give dose of two drugs that, administered three times a day for several days, might have a cumulative action. 10. What is the physiologic action of ergot on involuntary muscle? Nitroglycerin on peripheral blood vessels? Strychnia on the nervous system?

MATERIA MEDICA—HOMEOPATHIC (AUGUST).

1. Give the characteristic skin symptoms of graphites. 2. Give the neuralgic symptoms of colocynth. 3. Differentiate china and ipecac in hemorrhages. 4. Differentiate in general between belladonna, hyoscy. and stramon. 5. Give indications for two remedies in typhoid. 6. Describe the general effects of opium. 7. Give two remedies acting on the liver, with special indications. 8. Give brief outline of the action of quinin. 9. Give two remedies in the treatment of erysipelas, with indications. 10. What symptoms indicate sanguinaria in headaches?

MATERIA MEDICA AND THERAPEUTICS (JULY).

1. What do you understand by the cumulative action of a drug? 2. What are the modes of administration of medicine, and how does the dosage vary as compared to that of the mouth? 3. Give three drugs and their dosage that, in their excretion by the kidneys, will (*a*) render the urine antiseptic; (*b*) render the urine alkaline in reaction; (*c*) render the urine acid in reaction. 4. Name two drugs that will increase the secretion of bile by the liver cells (direct cholagogues), two that increase the flow of bile from the gall bladder into the intestinal tract (indirect cholagogues). 5. Compare the physiologic action on the heart of digitalis with strophanthus. 6. What would you consider a safe initial dose of hydrochlorate of cocain administered hypodermatically to an adult? 7. Compare the physiologic action of hyoscyamus with belladonna on the nervous system. 8. Give the medium adult dose of the following: Sulphate of morphin, tincture of belladonna, sulphate of strychnia, nitrate of silver, corrosive sublimate. 9. What is the composition of the following: Dover's powders, Fowler's solution, Basham's mixture? 10. What do you understand by the incompatibility of drugs? Name the general incompatibilities of iron.

MATERIA MEDICA AND THERAPEUTICS—ECLECTIC (JULY).

1. Give therapeutic application of digitalis—jaborandi and hyoscyamus. 2. Give indications and contraindications for morphia and chloral hydrate. 3. Give indications for strychnia. How would you give it and in what dose? 4. Give indications for aconite, veratrum, strophanthus, macrotys, and bryonia, with physiologic effect of each. 5. What is materia medica? Therapeutics? 6. How does gelsemium quiet a restless, fretful patient? 7. Differentiate a muriatic and nitric acid tongue. 8. What do you understand by the term alteratives: expectorants? 9. Specific diagnosis; specific medication. Define each, and on what are they based? 10. What form of medicine do you prefer, and why?

BACTERIOLOGY (AUGUST).

1. Name two anaërobic bacteria, and give a method of cultivating this class of bacteria. 2. Give the characteristics of anthrax bacilli. 3. Name three acid-resisting bacteria. 4. Name two ways by which bacteria propagate. 5. What is necessary to prove the pathogenic rôle of a pathogenic micro organism? 6. Give the differential bacteriologic diagnosis of typhoid and colon bacilli. 7. Describe gonococci, and give method of staining and method of culture. 8. What is Gram's solution, and how is it used? 9. What precautions are necessary in handling specimens that are to be examined for bacterial infections? 10. What bacteria are found in gangrene?

BACTERIOLOGY (JULY).

1. What do you understand by the terms toxins, ptomains, leucomains? 2. Bacteria, being devoid of chlorophyll, must obtain their nitrogen and carbon from what source in general? 3. In addition to carbon and nitrogen, what substance is required for the life and development of bacterial growth? 4. Define anaërobic, aërobic and facultative bacteria. 5. Name the three classes of bacteria as to form; illustrate each. 6. How are the micrococci subdivided, as seen in growing culture? Illustrate. 7. What is the difference between sterilization and disinfection? 8. What is an antiseptic, a germicide? Give examples of each. 9. What organism is generally accepted as the infective factor in puerperal septicemia? 10. Discuss the conditions necessary to infection; also give your ideas as to prevention of same, with method of disinfection.

PHYSIOLOGY (JULY).

1. What is meant by the proximate principles of the body, and how are they classified? 2. What is the composition of the gastric juice? In normal digestion what is the reaction shortly after taking food? 3. What is the action of pancreatic juice on albumin? Starch? Fats? Cane sugar? 4. What is considered a normal ratio in numbers between white and red blood corpuscles? How modified by prolonged exertion? By a hearty meal? 5. What is supposed to cause the first sound of the heart? The second sound? What constitutes a cardiac cycle? 6. What is average amount of air taken into the chest at each inspiration? 7. What is the average amount of water excreted in the urine in 24 hours? Urea? Uric acid? 8. What is glycogen? Give its origin and use. 9. What changes occur in the feces from obstruction of the common bile duct of the liver? 10. What is understood by reflex action? Illustrate by a drawing.

PHYSIOLOGY (AUGUST).

1. Name the digestive fluids found in the alimentary canal, and tell where each is produced. 2. Describe the circulation of the blood and give the causes of its flow in the different vessels. 3. Name the different organs concerned in the excretion of waste material of the body and give the principal ingredients eliminated by each. 4. Describe the lymphatic system and give its functions. 5. Name the principal divisions of the brain. 6. Describe the process of respiration. 7. Describe reflex action. 8. Describe stomach digestion. 9. Describe the portal circulation. 10. Name the cranial nerves and the function of each.

SURGERY (AUGUST).

1. Define fracture; compound fracture; comminuted fracture; impacted fracture; intracapsular fracture. 2. How would you recognize and dress a supracondyloid fracture of the humerus? 3. How would you treat a punctured wound; a lacerated wound? 4. Name different measures by which you would control hemorrhage in wounds. 5. In venous hemorrhage requiring surgical interference: First. How would you diagnose same? Second. What would be your treatment, and on what would it depend? Third. What are the special dangers in wounds of the internal jugular, subclavian, axillary, femoral and popliteal veins? 6. What is an irreducible hernia? A strangulated hernia, and how would you treat the latter? 7. Give the procedure, or steps, of an operation for inguinal hernia in the male. 8. Define phlegmon and outline treatment. 9. Give an example of a connective tissue tumor; an epithelial tumor; a dermoid tumor; a cystic tumor. 10. Differentiate chancre and chancroid under the following heads: Origin, incubation, situation, commencement, number, shape, surface, secretion, induration, sensibility, histology bubo.

SURGERY (JULY).

1. Arrange a grouping (*a*) showing principal benign tumors, (*b*) principal malignant tumors. 2. Differentiate a bilious colic and

right-sided renal colic. 3. Describe a chancroid. Give its usual symptoms and possible complications. 4. What are the causes of acute prostatitis? Describe a typical case, and give its treatment. 5. Describe the varieties of hemorrhoids, and give your treatment of any one variety. 6. Describe the osseous lesions of syphilis. 7. What is a tumor? Give the causes of tumors. Define homolgous tumor; heterologous tumor. 8. Describe the common forms of club-foot. Give the treatment of any one form. 9. Define shock. Give causes and symptoms. 10. Describe a method of skin-grafting. Under what conditions is skin-grafting employed?

ANATOMY (AUGUST).

Answer any 10 questions, but no more. 1. Describe the male urethra. 2 Describe the prostate glands, giving form, position, structure, blood and nerve supply. 3. Name several forms of hernia, giving the covering of oblique inguinal and femoral from within outward. 4. Name the ductless glands. 5. Describe the ileocecal valve. 6. Describe the clavicle, giving its structure and articulations. 7. What is the thorax, what does it contain, and of what is it formed? 8. Name the branches of the fifth nerve, giving general distribution of each. 9. Bound the abdominal cavity; name its contents and apertures, and what do they transmit? 10. Describe the peritoneum, and what does it invest? 11. Describe the lungs, giving structure, blood and nerve supply. 12. Describe the elbow joint, giving its articulations and ligaments. 13. Name the subdivisions of the alimentary canal, with its accessory organs. 14. Name the cranial nerves of special sense, and those of motion. 15. Name the three classes of articulations, giving examples of each.

ANATOMY (JULY).

Answer any 10, but no more. 1. What bones form the ankle joint? 2. Describe the thoracic duct. 3. The uterus, giving normal position. 4. The fallopian tubes. 5. The rectum. 6. The colon. 7. What are the branches of the axillary artery? 8. Give points of selection for ligation of axillary artery. 9. Give points of selection for ligation of subclavian artery. 10. What are the appendages of the skin? 11. What is the mesentery? 12. Locate and describe the prostate gland. 13. What viscera in the right hypochondriac region? 14. In the epigastric region? 15. In the hypogastric region?

OBSTETRICS (JULY).

1. What is menstruation? Give its clinical course, and describe the changes which take place in the endometrium. 2. How do you measure the conjugate diameters of the pelvis, and what degree of contraction is compatible with spontaneous delivery? 3. How may pregnancy be recognized in the early months, and on what evidence may the diagnosis be justified? 4. Give the vertex presentations in the order of their frequency and the mechanism of the most common. 5. What antiseptic measures should be employed in the conduct of labor, and how should they be carried out? 6. Describe the propelling forces in labor, and give the causes and treatment of inertia. 7. What are the indications for and rules to be observed in the use of obstetrical forceps? 8. Give the causes, signs, symptoms and treatment of puerperal sepsis. 9. What is involution, and how long a time is required for this process? 10. What is mastitis? Give its symptoms and treatment.

OBSTETRICS (AUGUST).

1. Give the diameters of the normal fetal head at full term. 2. Describe the formation of the placenta, and give the management of (*a*) retained placenta after abortion, (*b*) retained placenta after normal labor at full term. 3. Describe the fetal circulation, and state what changes take place in it at birth. 4. Give two possible physiologic causes of icterus neonatorum and differentiate the pathologic and physiologic forms. 5. Diagnose and give the prognosis and management of a breech presentation. 6. Give the pathology, prognosis and treatment of puerperal eclampsia. 7. How would you manage a case of labor at term with membranes ruptured and cord presenting? 8. Name the principal causes of sterility. 9. What results are likely to follow an unrepaired laceration of (*a*) the cervix uteri, (*b*) the perineum down to the sphincter ani? 10. What conditions should govern the use of anesthesia in labor? What anesthetic would you use, and why?

PATHOLOGY (AUGUST).

1. Name three predisposing causes of disease, and give example of each. 2. Define hypertrophy, hyperplasia, edema, anasarca, ascites. 3. Describe a diphtheritic inflammation of a mucous membrane. 4. Name the causes of hypertrophy of the liver. 5. Enumerate the causes and varieties of meningitis. 6. Name the causes, and give pathologic description of phlebitis. 7. What is the pathology of tabes dorsalis? 8. Describe the lymphatic involvement in an advanced case of carcinoma of the breast. 9. Examination of microscopic specimens. 10. Examination of pathologic specimens.

PATHOLOGY (JULY).

1. Describe the laboratory methods of service in the diagnosis of tubercular meningitis. 2. Enumerate the varieties of non-diabetic glycosuria. 3. In what conditions may eosinophilia be present? 4. Describe the character and extent of the lesions found in ischiorectal abscess. 5. Give causes and the most frequent localization of brain abscess. 6. Enumerate the causes of anuria. 7. Describe lipoma, and give its most frequent locations. 8. Define and describe surgical shock. 9. Examination of gross pathologic specimens. 10. Examination of microscopic sections.

CHEMISTRY (JULY).

1. What is the antidote for concentrated lye? 2. Why should fats or oils be avoided in phosphorus or phenol poisoning? 3. What element is indicated in anemic conditions? 4. Why is the blood saline? 5. Name the two normal pigments in the bile. 6. Why is toast more digestible than untoasted bread? 7. Calcium carbonate is an essential component of what parts of the human economy? 8. Where does protagon occur in the body? 9. What acid is found in sweat? 10. Name a carbohydrate that occurs in the urine pathologically.

CHEMISTRY (AUGUST).

Answer any 10, but no more. 1. State the law of definite proportions; of multiple proportions; illustrate each law by example or formulæ. 2. Define the words acid, base, salt. Name and define three classes of salts. 3. Give formulæ for (1) carbon monoxid, (2) carbon dioxid, (3) mercurous chlorid, (4) mercuric chlorid, (5) sodium sulphite, (6) ferrous sulphate, (7) hydrogen dioxid, (8) potassium permanganate, (9) nitric acid, (10) ethyl oxid. 4. Give the names, symbols and properties of the four elements classed as haloids. 5. Give the names, symbols and properties of the elements classed as alkali metals. 6. What is the effect of heat (to redness) on calcium carbonate? What produces the "hardness" of certain waters, and how does boiling soften them? 7. Describe a commercial process for the manufacture of sodium carbonate. 8. Describe two tests by which the mercurous salts may be distinguished from mercuric salts. 9. Define the following class names: (1) Hydrocarbons, (2) alcohols, (3) aldehyds, (4) organic acids, (5) ethers, (6) compound ethers, (7) carbohydrates, (8) amines. 10. Classify the following substances: (1) Marsh gas, (2) tallow, (3) chloral, (4) glycerin, (5) carbolic acid (phenol), (6) glucose, (7) iodoform, (8) benzine, (9) salol, (10) strychnin. 11. What is the normal reaction of fresh urine? How would you differentiate between alkalinity from fixed alkalies and alkalinity from decomposition? 12. Describe a quantitative test for urea. 13. Explain the formation of a phosphatic calculus with a uric acid nucleus. 14. Describe Fehling's test for sugar, and state the chemical property of glucose on which it is based. 15. In testing for albumin by heat, what other substance may cause a cloudy precipitate, and how may its presence be determined? In testing for albumin by nitric acid what other substance may cause a cloudy ring, and how may its presence be determined?

THEORY AND PRACTICE—HOMEOPATHIC (JULY).

Answer any 10 questions, but no more. 1. Define ascites. What are the causes, and how would you differentiate it? 2. Differentiate appendicitis, gallstone colic, and small right ovarian cyst with twisted pedicle. 3. Diagnose and treat a catarrhal enteritis. 4. Diagnose and outline treatment for obstruction of the cystic duct and of the common bile duct. 5. How would you recognize an internal hemorrhage, and what would you do for it? 6. What constitutes normal salt solution, and for what would you use it? 7. Define chalazion and blepharitis, and outline treatment for each. 8. What is anemia, and how would you treat it? 9. Diagnose and treat an acute nephritis. 10. What is marasmus? Outline general care of 6-month-old child so afflicted. 11. Give, briefly, your views in relation to baths—hot, warm, or cold—for the sick, how and for what you use them. 12. Diagnose pleurisy; give its complications. Outline treatment, medicinal and otherwise. 13. What is herpes zoster? Give causes and treatment. 14. What is a boil? What is a carbuncle? Give treatment for each. 15. What do you regard as the most worthy and important object in the practice of medicine?

THEORY AND PRACTICE—HOMEOPATHIC (AUGUST).

1. Give etiology, clinical course and general treatment of facial erysipelas. 2. Outline your treatment in a case of acute articular rheumatism. 3. Differentiate carefully between intercostal neuralgia, myalgia and pleurisy. 4. Give general and remedial treatment in an early case of diabetes mellitus. Prognosis? 5. Give symptoms and treatment of cholera infantum. 6. Give etiology, symptoms and treatment of angina pectoris. 7. Define goiter, giving treatment and prognosis in exophthalmic variety. 8. Give etiology and symptoms of a mitral and an aortic regurgitation. 9. Give etiology, symptoms and treatment of chronic cystitis. 10. Differentiate right renal colic from gallstone colic.

THEORY AND PRACTICE—ECLECTIC (JULY).

1. Give symptoms of intestinal infection, and name treatment for same. 2. How would you treat a tubercular knee? 3. Give treatment for pneumonia, with specific indications for each drug used. 4. When would you, and when would you not use poultices? 5. Name some of the common lesions of the heart, with remedies for the same. 6. What are some of the common causes of headache? Give treatment. 7. Write a prescription for pleurisy without effusion, where pain is sharp and increased by motion. 8. Diagnose a true case of diphtheria, and give indications for remedies. 9. What are the early symptoms of pulmonary tuberculosis as distinctive from a chronic pneumonia? 10. When does appendicitis cease to be medical and become surgical?

MEDICINE (AUGUST).

1. Differentiate varicella and variola; give a concise clinical history of each typical case. 2. What do you understand by enteroptosis; what are the common pathologic conditions involved? 3. Differentiate cancer of the stomach at an early stage, before any appreciable tumor, from catarrhal affections. 4. What is Hodgkins' disease; give symptoms and etiology. 5. Give a differential diagnosis of scarlet fever and measles. 6. Differentiate diphtheria and the various forms of tonsilitis at an early stage; give the treatment of diphtheria. 7. Give the etiology and pathology of tuberculosis of the intestines. 8. Give the differential symptoms of bronchiectasis and emphysema. 9. Describe the causative relations of syphilis and alcohol in atheromatous degeneration. 10. Give the clinical history of chronic parenchymatous nephritis and the urinary finding.

THEORY AND PRACTICE (JULY).

Answer any 10 questions. 1. Give diagnosis and treatment of acute purulent otitis media. 2. (*a*) Treatment of chronic follicular pharyngitis; (*b*) treatment of acute catarrhal laryngitis. 3. Give etiology, clinical history and treatment of cholera morbus. 4. How would you manage a case of acute gastro-intestinal catarrh in a child under 2 years old? 5. (*a*) Mention most common causes of constipation; (*b*) give treatment of chronic form. 6. What are the usual methods employed in examination of feces, and mention the clinical importance of each. 7. Give symptoms and treatment of acute cystitis. 8. Define and give symptoms and treatment of migraine. 9. Give etiology, characteristic symptoms and treatment of acute chorea. 10. (*a*) How would you recognize and treat diabetes mellitus? (*b*) Describe a diabetic blood test. 11. (*a*) Locate normal apex beat of the heart; (*b*) give diagnostic significance of displacement to the left; to the right; upward, and downward displacements. 12. Give treatment of eczema. 13. Give differential diagnosis of ascites and ovarian cyst. 14. Give diagnosis, prognosis and treatment of endometritis. 15. Write twenty lines on prophylaxis of pulmonary tuberculosis.

The Public Service.

Navy Changes.

List of changes in the Medical Corps of the Navy for the week ending Nov. 14, 1903:

Surgeon D. N. Carpenter, detached from the *Chicago* and ordered home to wait orders.

Asst. Surgeon R. B. Chapman, appointed assistant surgeon with rank of lieutenant, junior grade, from Oct. 28, 1903.

Surgeon O. Diehl, detached from the *Oregon* and ordered to the *New Orleans*.

P. A. Surgeon M. S. Guest, detached from the *New Orleans* and ordered to the *Oregon*.

P. A. Surgeon H. D Wilson, detached from the Naval Station, Olongapo, P. I., and ordered to the *Vicksburg*.

Asst. Surgeon G. M. Mayers, detached from the *Vicksburg* and ordered to the *El Cano*.

Asst.-Surgeon J. M. Brister, detached from the *El Cano* and ordered to the *Isla de Cuba*.

Surgeon C. Biddle, detached from the *Puritan* and ordered to the *Lancaster*.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 12, 1903:

Asst. Surgeon-General W. J. Pettus, detailed as inspector of unserviceable property in the Hygienic Laboratory.

P. A. Surgeon J. B. Green, granted leave of absence for twenty days from November 15.

P. A Surgeon J. F. Anderson, to proceed to Detroit for special temporary duty.

Asst.-Surgeon J. W. Trask, granted leave of absence for four days from Oct. 17, 1903, under paragraph 191 of the Regulations.

Asst. Surgeon T. W. Salmon, to proceed to Philadelphia and report to medical officer in command for duty.

A. A. Surgeon W. C. Mason, granted leave of absence for five days from November 19.

A. A. Surgeon Henry Owen, granted leave of absence for thirty days from November 8.

Pharmacist John Achenbach, granted leave of absence for seventeen days from November 20.

BOARD CONVENED.

Board convened at Chelsea, Mass., November 12, for physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, recorder.

APPOINTMENTS.

Thomas William Salmon of New York, commissioned (recess) as assistant surgeon, Nov. 7, 1903.

George Neves of Oklahoma, appointed pharmacist of the third class, Nov. 11, 1903.

RESIGNATION.

Pharmacist Frank Siedenburg resigned, to take effect Oct. 4, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Nov. 13, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Nov. 1-7, 2 cases.
Illinois: Belleville, Nov. 1-7, 11 cases, 1 death; Chicago, Nov. 1-7, 3 cases.
Indiana: Indianapolis, Oct. 25-31, 2 cases.
Louisiana: New Orleans, Nov. 1-7, 3 cases, 2 imported.
Maine: Grand Isle, Oct. 1-31, 25 cases.
Massachusetts: Haverhill, Nov. 1-7, 1 case.
Michigan: Detroit, Nov. 1-7, 2 cases.
Missouri: St. Louis, Oct. 25-31, 1 case.
New Hampshire: Manchester, Nov. 1-7, 5 cases.
New Jersey: Camden, Nov. 1-7, 1 case.
New York: New York, Nov. 1-7, 2 cases.
Ohio: Cincinnati, Oct. 31-Nov. 6, 1 case; Nov. 1-7, Cleveland, 1 case: Dayton, 2 cases; Warren, 1 case; Youngstown, 1 case.
Pennsylvania: Nov. 1-7, Erie, 1 case; Johnstown, 1 death; Philadelphia, 42 cases, 4 deaths; Pittsburg, 30 cases, 14 deaths.
Rhode Island: Providence, Nov. 1-7, 1 case.
Tennessee: Memphis, Nov. 1-7, 6 cases.
Utah: Salt Lake City, Oct. 25-31, 1 case.
Wisconsin: Milwaukee, Nov. 1-7, 1 case.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Oct. 11-24, 21 cases.

Mauritius: Oct. 2-8, 54 deaths.

Medical Organization.

Organization in Colorado.

J. M. BLAINE, M.D.
SECRETARY COLORADO STATE MEDICAL SOCIETY.

It should be remembered that the "backbone" of the continent passes through our state and that these spinous and transverse processes are not the best things in the world on which to found colonies and sustain vast populations; hence, one will find whole counties in this state where there are no physicians, and there are more than twenty counties in the state with from one to six physicians each. Under these circumstances it was thought best last year, when we adopted the new constitution, to modify it in one particular, viz., that persons in good standing in June, 1902, could remain members of the state society by paying the usual dues.

There were in the state sixty-six members who were protected by this proviso, as they were not members of county societies. There was no provision made, however, for new members to join the society except through membership in a local society. After trying this plan for a year our house of delegates, at the recent meeting in October, amended Chapter I, Article 11, of the by-laws so that there is now no membership in the state society. We made provision for the aforesaid "sixty-six" so that they could join the nearest county medical society without paying an initiation fee, provided the secretary of the state society would certify to their standing. This puts Colorado in line with the other states on the American Medical Association plan.

This brings us down to the question of providing local societies at convenient points throughout the state so that our men may not lose their standing in the American Medical Association.

When the new constitution was adopted there were ten county societies in the state. These were furnished with the model constitution sent out by the American Medical Association committee, and each one adopted it. In addition to these, we have, during the past year, organized seven new societies. Owing to the vastness of our state and the distances between centers of population, our councilors have delegated the work of organization to the secretary. This is a pleasant duty, and as a rule the work is very easy, for the physicians appreciate the fact that under the reorganization scheme a county society means something, as it carries with it representation in the state society, and is the only portal to the American Medical Association.

Last summer I received a letter from a physician in the southern part of the state asking how to join the state society. I answered that he could either join the nearest county society, which was 140 miles away, across a mountain range, requiring him to travel on three different lines of railroad, or organize a society of their own. I wrote to one of our prominent physicians living in that part of the state, and he took the matter up, and by combining five counties he organized a splendid society with 15 charter members. I received

the program of their last meeting and it would compare very favorably with a program of any society.

Last July I visited five counties and organized four societies, in one instance combining two counties. With three more societies (one of which is now under way) the "Western Slope" will be thoroughly organized, and I expect by our next meeting to be able to report societies organized in every available center.

In addition to the amendment mentioned, the house of delegates relieved the secretary from being chairman of the publishing committee and appointed a committee of three, with instructions to establish an official journal in which should be published the papers presented at the annual meeting and other matters of interest to the society. The section relating to membership in county societies was amended to read as follows:

Every reputable and legally qualified physician residing in this county who does not practice or claim to practice and agrees not to practice sectarian medicine, and who is not affiliated with a sectarian school or society, shall be eligible for membership.

This, we think, is a little stronger and better defined than the model furnished by the committee.

Up to June, 1902, when the new constitution was adopted, we had a total membership of 340. At our recent meeting in October the chartered county societies showed a membership of 554, and I expect to be able to report at our next meeting (October, 1904) that our membership has doubled.

Under the old system our dues were $5 per year. Under the new, and for the present, we assess each county society $3 per capita, so our revenue will be more than formerly.

We like the new plan. It has doubled our membership and unified the profession in the state, so that we will be in position to demand more courteous treatment at the hands of "Jim Crow" governors who have not enough gray matter in their brains to see the benefit of a good medical bill, or enough starch in their spinal cords to sign it; but, best of all, it constitutes the county society judge, jury and executioner and forces a man to be ethical at home before he can be a member of the state or national society.

California.

VENTURA COUNTY MEDICAL SOCIETY.—The medical men of the county met at Ventura, October 29, Dr. H. Bert Ellis, Los Angeles, president of the state society being present, and organized a county society with the following officers: Dr. John H. Love, Ventura, president; Dr. George A. Broughton, Oxnard, vice-president, and Dr. A. A. Maulhardt, Oxnard, secretary and treasurer.

Illinois.

MASON COUNTY MEDICAL SOCIETY.—This society was organized in Havana the first week in November with the following officers: Dr. Philip L. Diefendacher, Havana, president; Dr. Edward W. Paul, Forest City, vice-president; Dr. Harry H. Hanly, Havana, secretary, and Dr. C. Fred Grimmer, Topeka, treasurer.

Iowa.

SHELBY COUNTY MEDICAL SOCIETY.—On October 30, the physicians of the county met at Shelby and organized a county society with twelve charter members, and the following officers: Dr. N. Jasper Jones, Shelby, president; Dr. Eugene J. Smith, Harlan, vice-president, and Dr. Hennesy, Panama, secretary.

Louisiana.

ST. JAMES' PARISH MEDICAL SOCIETY.—At the meeting for organization, October 31, Dr. Peter C. Tircuit, St. Patricks, was elected president; Dr. Louis A. Gaudin, Convent, vice-president, and Dr. J. F. Buquoi, Colomb, secretary and treasurer.

CALCASIEU PARISH MEDICAL SOCIETY.—This society was formally organized on the standard plan, November 2, at Lake Charles, with the following officers: Dr. Allen J. Perkins, Lake Charles, president; Dr. Perrault, Jennings, vice-president, and Dr. Pearl Munday, secretary and treasurer.

ASSUMPTION PARISH MEDICAL SOCIETY.—The physicians of the parish met at Napoleonville, October 22, were addressed by Dr. John M. Barrier, Delhi, president of the Louisiana State Medical Society, and organized a parish medical society on the standard plan, with the following officers: President, Dr. Thomas B. Pugh, Napoleonville; vice-president, Dr. Adolphe A. Aucoin, Plattenville, and secretary and treasurer, Dr. Adrian A. Landry, Paincourtville.

North Carolina.

WAYNE COUNTY MEDICAL SOCIETY.—This society was reorganized at Goldsboro, October 26, with the aid of Dr. Albert Anderson, Wilson, councilor for the Fourth District. The following officers were elected: Dr. Marcus E. Robinson, Goldsboro, president; Dr. William Spicer, Goldsboro, vice-president; Dr. William H. H. Cobb, Jr., Goldsboro, secretary; Dr. Theodore L. Ginn, Goldsboro, treasurer; Drs. William H. H. Cobb, Goldsboro, J. B. Kennedy, and William T. Turlington, Fremont, censors, and Dr. John F. Miller, delegate to the Medical Society of the State of North Carolina.

Society Proceedings.

COMING MEETINGS.

Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 15.

Western Surgical and Gynecological Association, Denver, Dec. 28-29.

COLORADO STATE MEDICAL SOCIETY.

Twenty-Third Annual Convention, held in Denver, Oct. 6-8, 1903.

(*Continued from page 982.*)

Osteo-arthritis and Rheumatoid Arthritis.

DR. B. C. LEAVITT, Denver, thinks that the two affections are often confounded. The severe cases of osteo-arthritis, he asserts, would not have reached this stage of they had been properly treated. As soon as the disease is recognized they should receive a tonic treatment, meat and fresh air being especially indicated. The joints should be wrapped in moistened gauze, covered with rubber tissue. They should be treated as tubercular patients. Going to Hot Springs has no medicinal value.

Incipient and Acute Insane—Recoverability and the Factors Therein.

DR. J. E. COURTNEY, Denver, asserts that the most important factor for recovery is the earliest possible recognition and treatment. The statistics of institutions are all uniform on these points. The percentage of recovery in which the attack has existed three months or less, is upward of 50 per cent. of all recoveries, and after a duration of six months previous to admission the recovery rate falls.

Soup Diet in Typhoid Fever.

DR. H. B. WHITNEY, Denver, fed 17 of his patients suffering from typhoid with soup. With the exception of one case that died from meningitis they were singularly devoid of either severe toxic gastro-intestinal symptoms; no delirium, sleeplessness, dry tongue, tympany or diarrhea. The diet was well borne. The soup is prepared according to the following formula: Five pounds of meat is put in 10 quarts of water, brought to a boil and skimmed. One pound of pearl barley is added, the whole is cooked for six hours, strained and seasoned. The patient received 40 ounces of the soup between 7 a. m. and 7 p. m.

The Treatment of Neurasthenia.

DR. HOWELL T. PERSHING, Denver, divides the remedies into (a) those whose chief effect is to prevent the loss of nervous energy—prevention of emotional disturbances by reassurance and favorable suggestion, by forming a habit of relaxation and repose, limitation of work, prevention of toxic condition, removal of peripheral irritation, reduction of cortical irritability by medicine, and sleep; (b) remedies whose chief effect is to increase the income of nervous energy—food and medicines, and (c) remedies used empirically whose action is complex or obscure—electricity, hydrotherapy, massage, exercise.

The problem of selection and combination of remedies the physician must approach in the spirit of an artist rather than in that of a pure scientist. His greatest skill will be demanded by those who are not financially able to command the luxuries of the rest cure and who must return to their work.

Case of Hysterical Hyperpyrexia and Hemoptysis.

DR. BERNARD OETTINGER, Denver, reported the case of a man 24 years old sent to Denver with diagnosis of tuberculosis.

On admission to the Jewish Hospital for Consumptives slight dullness at base of right lung could be detected, but no râles. He coughed up bloody mucus at times. Temperature normal. He was put to bed, and on the same day the thermometer registered 108 F. Two days later the temperature record was 114 F. by mouth and rectum. Complains he can not see well. Complete ptosis of right lid. Papillary reaction sluggish. Complete anesthesia over top of head, chest, back and shoulders. All possible points of deception or simulation were considered and excluded.

A Case of Congenital Dilatation of Colon.

Dr. C. K. Fleming, Denver, reported the case of a man 25 years old who suffered from chronic constipation from infancy. He was 8 days old when he had his first bowel movement, 80 days when he had the second movement. From the second year his bowels moved about four times a year. His movements were very large. Relief from distention could only be obtained by the use of rectal tube and prolonged irrigation.

During the intervals he felt perfectly well. The patient consented to an exploratory laparotomy. On opening the abdomen a large collapsed colon was readily found and delivered from the abdominal cavity. In color it resembled an ovarian cyst; it extended about 3 inches below splenic flexure to the anus, involving the descending colon, sigmoid and rectum. The operation consisted in plaiting the sac longitudinally from one extremity to the other. Seven or eight folds were taken. The plicated sac was suspended by a catgut suture to the abdominal wall. Convalescence was uninterrupted. His bowels move by cathartics daily, which was never possible before the operation.

Congenital Dislocation of Hip.

Dr. George B. Packard, Denver, reported the histories of six cases, three of which were operated on by Professor Lorenz and three by the author. Three of the cases gave good results and three produced anterior transpositions.

Injuries of the Elbow Joint.

Dr. C. B. Lyman employs plaster-of-paris splints made of 8 or 10 thicknesses of gauze, saturated thoroughly in liquid plaster of paris, one to extend from axilla to fingers, the other from neck to fingers. These are applied next to the skin and secured by roller bandage. The arm can then be flexed to any angle desired. The arm is then held in that position until the splints become hard. He does not believe in passive motion.

Radium.

Dr. G. H. Stover exhibited some radium chlorid and described various experiments which he made. He applied it in three cases of cancer, but so far the results were not satisfactory. He thinks radium will never equal the *x*-ray for skiagraphic work, nor probably as a therapeutic agent.

The Passing of the Curette and Douche.

Dr. H. G. Wetherill, Denver, maintains that the curette and bichlorid douche should not be used in acute infection of the female genital organs. They are unnecessary and universally injurious. The patients that have recovered after such operation have done so in spite of the treatment. The treatment he uses as a substitute is the flushing of the uterus through a double drainage tube with alcohol of varying strength, according to the severity of the symptoms and the degree of smarting it produces at the vaginal outlet. This is a modification of the alcohol method of Corossa. This treatment is used in the Woman's Hospital for all intrauterine infections after abortion, complete or incomplete, or labor or term.

Report of a Case of Nephro-ureterectomy.

Dr. Chas. H. McLean, Denver, reported the case of a man aged 72 years, who 30 years ago had an attack of excruciating pain in the region of left kidney extending to penis and left testicle, lasting one day and terminating rather abruptly. Ten years ago had another such attack, and since had renal attacks about every six months.

A year ago during an attack had a hemorrhage from kidney, and passed blood every two or three months since, accompanied by paroxysms of pain, nausea, chilliness and light fever. For last two or three months the hemorrhage is continuous. Patient consented to an operation. The kidney was found normal. A sound passed into the urethra met with an obstruction in the region of the pelvic brim. The ureter was found bent on itself and held firmly by adhesions. After separating the adhesions an attempt to pass the sound was not successful on account of thickening and tumefaction. The kidney and ureter were excised. Patient made good recovery.

Therapeutics of Whooping Cough.

Dr. J. Tracy Melvin, Sagauche, enthusiastically recommended the use of antipyrin internally and also as a spray of a 4 per cent. solution. He used exclusively this treatment in 14 cases, all of whom recovered in from twenty-two to twenty-six days. He supplements the antipyrin treatment with loading the inhaled air with vapor of creosote, pure and crude carbolic acids.

Specifics and Specific Treatment in Treatment of Pulmonary Tuberculosis.

Dr. S. Simon, Denver, presented a historical review of measures and methods which have been considered specifics in their time and generation. He concludes with the statement that he does not believe "there is or ever will be any one remedy which will prove specific." He thinks the one great therapeutic measure which is almost specific is plenty of pure aseptic air.

Treatment of Tubercular Ulceration of Rectum and Perianal Region.

Dr. P. Mayhew, Colorado Springs, treats the above condition as follows: He paints the ulcer with a saturated solution of trichloracetic acid. The next day this is repeated, and after waiting a few minutes for the acid to act the follicle of tissue which has been destroyed is removed with curette. No anesthetic is required. This may be repeated if necessary. The ulcer is dressed with iodin-carrying powders. The patient should be seen every other day. If healthy granulations have appeared there is no necessity of using the acid any more; Lugol's solution may be used instead. The tubercular ulcer is ultimately converted into a simple ulcer. The patients are apt to complain of increased soreness and painful defecation. This is really a sign of increased health.

Cholecystectomy vs. Cholecystostomy.

Dr. Maurice Kahn, Leadville, advocates the entire removal of the gall bladder whenever it is found diseased; he considers it a useless organ, "a settling basin for stone formation, and a suitable harbor for the multiplication of pathogenic bacteria." He operated on a woman 23 years of age who was treated for stomach trouble for several years. The gall bladder filled with pus and stones, was removed. The patient was out of bed 14 days after the operation.

A Case of Multiple Depressed Fracture of the Skull. Recovery.

Dr. S. D. Van Meter, Denver, reported as follows: Male, aged 40. Foreman. While repairing a shafting box was struck on the left side of the head, about center of squamous portion of temporal bone by the end of an iron buck-stay, 11 feet in length, which fell from an upright position, the dead weight of which was estimated at 150 pounds. It struck with sufficient force to drive the injured man's head against the shafting of an upright bolt hard enough to cause two depressed fractures at the point of contact, and fracture at base of brain. The depressed fragments were removed. The first 5 days he lay in a stupor, but there were no signs of compression. At the end of the second week the nurse was able to get him to take some water and liquid food by the mouth. In another week he was able to take sufficient food by the mouth to sustain him. During the sixth week he began to use the vessel for urination and defecation, and commenced to walk.

Dr. Howell T. Pershing, Denver, describes the defects of speech and mind as follows: He hears words but does not understand them; his speech is a jargon made up of words correctly uttered, of others mutilated, and of still others en-

tirely unintelligible, although intended for words. He is word-deaf for his own speech and for that of others. Both reading and writing are defective.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Proceedings of the Thirty-first Annual Meeting, held at Washington, D. C., Oct. 26 to 30, 1903.

(*Concluded from page 1224.*)

Characteristics of the Stegomyia Fasciata which Affect the Conveyance of Yellow Fever.

DR. H. R. CARTER, Baltimore, read this paper and gave the following summary, among the special characteristics of the stegomyia, which affect its rôle as a carrier of yellow fever:

1. Its distribution is, generally, between latitudes 43 N. and 43 S. on the coasts and low plains of Africa, Asia and the adjacent islands; Australia and the Mediterranean basin of Europe. It is also general on the eastern coast of America from 38 N. to 35 S. latitude. On the west coast it is found at Panama and Guayaquil, and its existence is implied from Guaynquil to Acapulco. In the United States it is general on the coast and low plains of the southern states, except Maryland.

2. It is conveyed by vessels indefinite distances (from Cape Town to Savannah quarantine); in much greater numbers and more often by sail than by steam vessels.

3. It lives a long time—154 days being recorded by Guiteras of an infected insect.

4. Once having acquired the power of transmitting yellow fever, it retains it apparently as long as it lives—59 days being recorded.

A consideration of the four postulates above will render it advisable to safeguard the tropical countries of the East when communication is opened up between them and American ports infected with yellow fever, preferably by freeing the American ports of yellow fever.

5. It propagates preferably in artificial containers, but will propagate in pools where such containers are not available.

6. In America it has been reported only in the vicinity of human dwellings, and seems here not to be a sylvan, paludal or campestral mosquito.

The war against this insect in America should, therefore, be waged about the houses of men, and especially against water in artificial containers. The introduction of a water supply, piped to every house, so as to do away with cisterns and water jars, is the most important measure of sanitary engineering to free a town of this mosquito. Next to this is a system of drainage by covered drains to carry off the rain water and prevent pools. Cesspools are not objectionable on this score.

The stegomyia unquestionably hybernates in the United States, either as adult larva or egg, but if the infected adult hybernates, either a very large proportion of them die, or else the infecting parasite must generally die in the hybernating mosquito. The first seems more probable.

7. It is essentially a house mosquito, and is inclined to stay about the premises where it has fed. Hence, the greater safety of the wholesale district of an infected city as compared with the residence portion.

8. It does not feed in the dark or in bright sunlight. Therefore, in bright daylight or at night without artificial light are the safest times to be in an infected place.

9. The cycle of the yellow fever parasite in the mosquito before it can be conveyed to man is generally, in hot weather, about 14 days or over. Prior to the accomplishments of this cycle (once called the "extrinsic incubation of yellow fever") the mosquito can not convey this disease.

10. It is probably usually conveyed aerially less than 100 yards. In Havana the infected insect is believed to be never aerially conveyed 1,500 feet from the Havana shore.

The direction of the prevailing wind during the day influences its aerial conveyance.

The Effect of Lemon Juice in the Mixture Known as Lemonade on Typhoid Polluted Water.

DR. WILLIAM J. BISSELL, Buffalo, N. Y., read this paper as the result of an investigation prompted by a newspaper statement purporting to be from the Chicago Board of Health to the effect that lemonade would kill the typhoid bacilli. The conclusions drawn were: 1. Lemonade can not be depended on in this rôle. 2. This method of sterilizing typhoid polluted water should be discouraged.

Sodium Sulphite—A Dangerous Food Preservative.

DR. CHARLES HARRINGTON, Boston, said that sodium sulphite is used very extensively as a food-preservative, and, more particularly, for its effect on the color of chopped meat (Hamburg steak) and certain canned vegetables (asparagus and corn). Experiments show it to be a dangerous addition to food.

Studies of Media for the Quantitative Estimation of Bacteria in Water and Sewage.

MR. STEPHEN D. GAGE and MR. GEORGE O. ADAMS, Boston, contributed a joint paper on this subject. Studies of the efficiency of water filters in removing bacteria when estimated by counts on different media, show that there is a considerable variation between the various media, the ratio between the numbers of bacteria in the raw water and in the effluent being affected by the period of incubation, the reaction and the composition of the media. The writers recommend that a standard nomenclature be adopted for the various culture media, the names used to express, as far as possible, the composition of the media.

The Value of Tests for Bacteria of Specific Types as an Index of Pollution.

MR. H. W. CLARK and MR. STEPHEN D. GAGE, Boston, read a joint paper with this title. The colon bacillus is the most numerous type in normal sewage and is accordingly of the most value as a specific indication of pollution. Bacteria of the colon type can be detected in ordinary city sewage in dilutions of 1 to 10,000 to 1 to 100,000. Surface waters having the greatest relative population on their watershed have shown bacteria of the colon type more frequently than others with less population. Ground waters, on the other hand, unless grossly polluted never show bacteria of colon type. Examinations for *B. coli* in different volumes of water show that tests in both one and 100 cubic centimeters should be made, the tests in larger volumes being confirmatory of the tests in the smaller volumes and in cases where a considerable number of samples are taken from the same source tests in the larger volumes usually give more information day by day as to the quality of the water than do the tests in one cubic centimeter.
